## 8. Exposure with Children and Adolescents

The adaptations for young people are not cosmetic. Each of them follows from a developmental fact, and a student should be able to state the fact and the adaptation.

### 8.1 Cognitive capacity and the prediction–outcome comparison

The central mechanism of contemporary exposure is the comparison of the young person's prediction with the observed outcome, and this mechanism requires a capacity to form a prediction, to hold it, and to compare. That capacity is still developing in a twelve-year-old and is weaker still in a young person with a learning difficulty or an intellectual disability.

The adaptations follow directly. The prediction is made explicit and written down, or drawn, so that the comparison is concrete rather than retrospective. The comparison is made immediately after the exposure rather than at the next session. The scale for rating distress is a visual analogue scale or a numbered scale rather than a verbal report. And with young people whose capacity for prediction is limited, the emphasis shifts further towards the behavioural components — the modelling, the graded practice, the repetition — which do not require the prediction at all.

### 8.2 The developmental gradient of the fear

Young people's fears are not distributed evenly across the developmental range, and the form the fear takes predicts the treatment.

**Early childhood.** Fears are concrete, specific, and largely realistic: monsters, the dark, thunder, doctors. Treatment is largely parental and involves graded exposure by the parent with the therapist as consultant, and it works well.

**Middle childhood.** Fears become more elaborate and more social. School phobia, often with somatic presentation, is a characteristic middle-childhood presentation, and the treatment involves a graded return to school with a specific first-day design, coordination with the school, and often a plan for the parents, whose anxiety is frequently the barrier.

**Adolescence.** Fears become more abstract and are more often embedded in identity: performance fears, social evaluation fears, fears about the future. The cognitive component of the exposure becomes more prominent, and the work on the feared self-image becomes more important, because at this age the feared outcome is frequently not a stimulus but an identity — being thought to be weak, thought to be a failure, thought to be nothing.

## 8.3 The developmental gradient of the control of the situation

A young person's control over the exposure varies enormously, and the treatment must be built around the actual degree of control.

**A very young child has no control.** The parent or the teacher controls the exposure entirely, and the therapist's role is to coach the adult. This is a common and underestimated form of behavioural work with young people, and the skill required is coaching adults rather than treating children.

**A mid-child has partial control.** The young person can choose the pace within a structure that others set, and a good treatment uses this: the adult establishes the non-negotiable elements, the young person controls the rest.

**An adolescent has substantial control, and the treatment should reflect it.** The exposure is designed collaboratively, the young person sets the goals, and the therapist's role is explicitly consultative. An exposure imposed on an adolescent is likely to fail for reasons that have nothing to do with the theory.

## 8.4 The role of the parent

The parent's role requires explicit thought, and the literature is clear that the parent's anxiety is one of the strongest predictors of poor outcome in the exposure treatment of children's anxiety.

Three practical rules follow. First, the parent is coached before the exposure begins, on what to say, what not to say, and how to respond to the young person's distress, and the coaching is specific. Second, the parent's own distress is addressed directly and compassionately, because a parent who is frightened of the school will inadvertently signal that the school is dangerous, and the young person will learn to read that signal. Third, the parent is given a role that is useful rather than a role that is anxious, which usually means a specific practical job in the exposure rather than a watching brief.

There is an important caution about the parental accommodation literature. Sustained parental accommodation of a child's anxiety is now understood to be a maintaining factor rather than a supportive one, and parents frequently need to be helped to stop accommodating. This is a hard message to deliver, and it should be delivered with the recognition that the parent has been doing the accommodating out of love, and with a great deal of support.

## 8.5 School refusal

School refusal is one of the most common referrals in school counselling and one of the most heterogeneous, and the behavioural framework requires that it not be treated as a single condition.

A functional analysis of the school refusal is the first step, and it distinguishes at least four patterns: refusal maintained by **escape** from a specific aversive school situation, often a bullying situation or a particular class; refusal maintained by **anxiety** about a specific social or performance demand; refusal maintained by **attention**, in which the attendance pattern has become a negotiation with the parents; and refusal

maintained by **somatic or medical symptoms**, in which the child is genuinely unwell and the school is the setting in which the illness is expressed.

Each of these has a different treatment, and the commonest clinical error is to treat all of them with the same graded return to school, which works for the escape-maintained case and fails for the others.

**The first-day design for school refusal** has a specific and well-described form: the return to a very brief, highly structured, and rewarding visit, often on a day when the feared class is not timetabled, and with a specific activity, a specific adult, and a specific reward. The young person returns to the building, does one specific thing, and leaves having had a good experience. The second visit is longer. The plan is written down and shared with the school, and the school must be ready to receive the visit.

### 8.6 Social anxiety and the school environment

Social anxiety in the school setting requires a plan that extends beyond the therapy room, because the feared situations occur in corridors, at break, in the dining hall, and in the classroom, and the treatment must involve the whole school.

The components of such a plan typically include: a designated safe adult; a pre-arranged escape route that the young person can use without it being a visible event; a rehearsal of the specific interactions with the peers concerned; a graded ladder of classroom participation; and, in many cases, a group-based social skills intervention, which is more effective than individual work for social anxiety and has the additional benefit of normalising the difficulty.

### 8.7 Adaptive and maladaptive response styles

Young people vary in how they respond to exposure, and three response styles are worth distinguishing.

**The healthy response** is fear that rises, peaks, and falls, with the young person remaining in the situation and observing the decline.

**The avoidance response** is the young person who is distressed, who then asks to leave, and who is allowed to leave. The escape is the treatment failure, and it is the most common one.

**The agitated response** is the young person who is distressed and who becomes increasingly agitated, aggressive, or distressed to a degree that the session cannot continue. This response requires a different approach, usually involving a lower first-day dose, a greater emphasis on modelling, and a slower grade.

A student who can distinguish these three responses in a session has acquired a clinically important skill.

## 9. Case Illustration: The Young Person Who Would Not Take the Lift

**Presentation.** Tomas is fourteen. He has not used the lift at his school for two years, and the consequence is that he arrives late every day, misses the first lesson, and is spoken to by the pastoral team. His mother reports that he will use the stairs at home, including in a six-storey building, but refuses the lift "because of the people."

The referral came from the school, which describes the problem as defiance. The first session with Tomas establishes that it is not.

**The assessment.** Two questions are asked before anything else is planned.

*What happens in the lift?* Tomas says that the lift is small, that there are usually other students in it, and that he is sure someone will notice him and say something. He describes in detail a sequence in which a group of boys from another year enter the lift, look at him, and start laughing. When asked how often this happens, he says "every time."

*What happened the first time?* This question takes some time, and the answer that emerges is that in his first year at the school, a group of students had been in the lift and one of them had said something about his shoes. He has never re-entered the lift alone since.

The anxiety and the avoidance are now clear, and the functional hypothesis is stated explicitly: **the behaviour — using the stairs — is maintained by escape from the feared social situation, and the escape is reinforced by the absence of the feared outcome and by the relief of the anxiety, and the young person's belief that the situation is genuinely dangerous is maintained by the absence of any disconfirming evidence, which the avoidance guarantees.**

**The plan.** The plan is built around the fact that the feared outcome is social, that the feared situation involves a small enclosed space with an uncontrollable group of peers, and that the young person has no evidence about what actually happens.

The first-day exposure is designed to be small and to be a success.

*Preparation.* Tomas is shown the lift interior in the school reception area, with a staff member standing beside it, and he walks past it twice. That is the whole of the first day. It is small enough that it is almost trivial, and it is selected because it will succeed.

*The second exposure.* On the following day, Tomas enters the lift with the pastoral support worker, goes down one floor, and exits. The counsellor has agreed in advance what will be said if anyone laughs, and has established with the head of year that there is a specific plan for the handling of any incident, because a plan that depends on nothing happening is not a plan.

*The third and fourth exposures.* Tomas enters the lift with a peer he chooses — a friend who does not make him more anxious — and stays for two floors. The friend's presence is a safety signal in the early phase and the purpose is to establish that the situation is survivable with another person present, and the plan to build toward the unaccompanied exposure is explicit from the start.

*The unaccompanied exposure.* By the second week, Tomas enters the lift alone, and the primary and secondary work of the treatment begins: the "checking" of the feared outcome, in which Tomas is asked after each exposure what actually happened, and the two behaviours he had never done, which are the ones that the avoidance was protecting him from. The first time he rides the lift with a group of boys in it and nothing happens, the session is over.

**The cognitive work.** The exposure is not only behavioural. Two beliefs are examined explicitly, because the exposure gives the young person the opportunity to disconfirm them and the therapist's job is to help him notice that he has.

*The catastrophic belief.* "Everyone will laugh." The check: after each exposure, what actually happened? The accumulated evidence is that in eleven exposures, one boy made a comment about a game he was playing on his phone. Tomas is asked to rate how much that comment had in common with his prediction. The discrepancy is enormous, and it is the discrepancy that constitutes the learning.

*The self-image belief.* "I am the kind of person who gets laughed at." This is the deeper target and the one that is not resolved by a single successful exposure. The work is on the difference between the old identity

— which was constructed in a specific incident in a specific year — and the young person's current account of himself, and it is done collaboratively, in the manner of the narrative work of Chapter 36.

**The school plan.** Tomas still arrives late, because the school day starts with a first lesson and he cannot realistically be at school before it. The school plan addresses this directly: the pastoral team arranges for him to have a quiet breakfast in the room of the form tutor before the first lesson, with the tutor available but not requiring conversation. The aim is to remove the punishing consequence of the lateness, which had been adding a substantial daily burden to the anxiety, and to prevent the avoidance from being reinforced by a second mechanism — the relief of not being noticed.

**The outcome and the interpretation.** Tomas uses the lift alone within three weeks, with an occasional deliberate re-exposure, and the work continues on the social evaluation belief for a further two months. His lateness continues and the school has agreed not to pursue it, which was a decision that required the counsellor to make the case for, and which was correct: the pursuit of the punctuality target would have provided a strong reinforcement for the avoidance.

Two features of this case generalise. The first is that the referral question ("defiance") and the presenting problem (avoidance) had nothing to do with each other, and that the functional assessment is what separated them. The second is that the exposure alone would not have been sufficient, because the young person needed a specific plan for the school environment, and because the plan for the lateness was as important as the plan for the lift. Exposure works within a context, and the context is usually doing as much work as the exposure.

# 10. Evidence and Research Support

## 10.1 The status of the evidence

The evidence for exposure-based treatments is among the strongest in the psychological literature, and it is strongest where the theory would predict it to be strongest: for specific, well-defined fears, with a clear functional relation between the stimulus and the fear, and with the avoidance behaviour as the target.

The key findings are as follows.

**Exposure is the best-supported treatment for specific phobias.** The evidence base is large, the effect sizes are large, and the treatment is brief by any standard.

**Exposure-based treatments are effective for panic disorder, social anxiety disorder, and obsessive-compulsive disorder**, and they are the first-line treatment for all three in most international guidelines, with the protocols specified in detail.

**Prolonged exposure is effective for post-traumatic stress disorder** in adults, with more variable evidence in children and adolescents, and the developmental adaptations are described in Chapter 39.

**The efficacy of exposure does not depend on the young person's insight.** The single most important finding in the comparative research is that psychoanalytic interpretation and exposure produce different results, with exposure markedly superior on the outcome measures that matter, and the finding has been replicated.

## 10.2 The evidence with children and adolescents

The evidence with young people is substantial and has grown considerably.

**Individual, clinician-guided exposure** has a large literature across the anxiety disorders of childhood, with meta-analyses reporting large effect sizes for the specific phobias, for social anxiety disorder, for generalised anxiety, and for separation anxiety. The age range extends down to young children in the case of the specific phobias, with parental involvement.

**Parent-delivered exposure** has good support in the specific phobias of childhood and has the advantage of generalising into the family environment, where the feared stimulus usually lives.

**School-based exposure programmes** have good support in school refusal and in social anxiety, and the group formats that include a teacher or a peer are more effective than those that do not.

**Intensive, residential, or clinic-based programmes** for severe school refusal have good support and are an important part of the service landscape, though they are resource-intensive and their availability varies.

**The treatment of OCD in children and adolescents** with exposure and response prevention has a strong evidence base, and the developmental modifications — which are considerable, and which are described in Chapter 25's companion material and in the OCD sections of Part VI — are well specified.

## 10.3 The component studies

The treatment is not a monolith, and the component literature is more instructive than the outcome literature.

**Repeated exposure beats single exposure**, which is the most firmly established component finding, and it is the foundation of the relapse-prevention work.

**Homework between sessions improves outcome**, and the finding holds across anxiety disorders and across age groups. The mechanism is generalisation.

**Predicting the outcome and checking it improves outcome**, and this is the finding that most clearly identifies the modern protocol as different from the classical desensitisation.

**Attention to the young person's predictions improves outcome**, and the studies show that the prediction–outcome discrepancy is the mechanism.

**Working with the therapist present is better in the early phase and worse in the later phase**, and the finding supports the standard clinical progression.

**In vivo is superior to imagery** in the specific phobias, and the finding is now unambiguous.

## 10.4 Limitations of the evidence

Four limitations should be stated honestly.

**The literature is dominated by individual, outpatient, motivated families.** The trials that generate the evidence are largely conducted in well-resourced settings with motivated participants, and the generalisation to a school caseload with reluctant families and logistical constraints is a genuine question.

**The follow-up periods are often short**, and the clinical observation — that the gains are maintained but that a proportion of young people relapse, and that a booster session is effective — is a clinical finding that the trials do not always capture.

**The measures are largely self-report**, which is a particular problem with children, whose reports of their own distress are unreliable in the direction that flatters the treatment, and the field's response has been the

use of behavioural observation measures, of which the school-based avoidance measure developed by clinicians and researchers in this area is the most widely used.

**There is a subgroup for whom exposure does not work well**, including young people with significant developmental disability, young people whose anxiety is a secondary phenomenon of an untreated trauma or of a family system that is continuing to be unsafe, and young people with high levels of parental accommodation. These are not failures of the treatment; they are indications that the assessment was incomplete.

# 11. Strengths and Limitations of Exposure-Based Work

## 11.1 Strengths

**It is the best-evidenced treatment in the field.** For specific phobias and for several other anxiety disorders, exposure has more evidence behind it than any other intervention, and this is a statement about the quality of the research as well as about the effectiveness of the method.

**It is brief and economical.** Many young people are treated in a small number of sessions, which matters greatly in services with long waiting lists.

**It is portable.** The principles transfer to any setting, and the method requires no equipment, no special room, and no specialist apparatus.

**It is compatible with other approaches.** A young person can receive exposure within a cognitive therapy, a behavioural therapy, a family therapy, or a school-based service, and the exposure component is identifiable and specific within it.

**It gives the young person something.** A successful exposure produces a piece of evidence, and the young person keeps it. The therapeutic alliance is often established in the first session by the treatment itself.

## 11.2 Limitations

**The early sessions are unpleasant.** The treatment works by producing distress, and a young person who is asked to endure distress deserves a practitioner who is honest about the fact and who is prepared to sit with them while it happens.

**The therapeutic relationship can be damaged by the treatment.** There is a period in every course of exposure in which the young person experiences the therapist as the person who is making them do the thing they most fear. The alliance usually recovers, and it recovers faster where the therapist has prepared the young person for that reaction in advance.

**It is easily misapplied.** A treatment that involves deliberately provoking fear can be used in ways that damage the young person, and the field's safeguards are designed to prevent exactly that. The recent history of poorly controlled internet-delivered exposure with adults is a warning, and with young people the stakes are higher.

**It does not address everything.** Exposure treats the fear. It does not repair a family system, undo a trauma, treat a depression, or resolve a conflict about authority. Chapter 33 and Chapter 38 address the cases in which the fear is embedded in a system that must also be addressed.

**The young person's motivation is a precondition, and it is not always present.** A young person who has no interest in overcoming the fear, or who is in an environment where overcoming it would be dangerous, is not a suitable candidate for the treatment as delivered, and the assessment of motivation is part of the assessment rather than an afterthought.

# 12. Cultural and Ethical Considerations

## 12.1 Culture, fear, and the meaning of avoidance

The question of what a young person is afraid of, and what the fear means, is culturally patterned in ways that the exposure model must not overwrite.

**Some fears are collectively held and socially sanctioned.** A young person who is afraid of the dark, of particular foods, of particular religious or cultural practices, or of particular social obligations, may be reflecting a shared and respected understanding of the world rather than an individual pathology. A treatment that extinguishes such a fear without understanding its social context removes the young person's connection to a community, and the young person will be supported in maintaining the fear by everyone around them.

**Some fears are real.** A young person who is afraid of a particular adult, of a particular neighbourhood, of a particular school corridor, or of a particular person in the family, is making a reasonable assessment of a real danger, and an exposure programme that confronts that stimulus without a safety assessment is a serious ethical failure. Every exposure plan requires an explicit check of whether the feared outcome is possible, and the discipline's protocols are explicit that exposure is contraindicated where the threat is real.

**Avoidance can be a cultural value.** Familial and community norms about modesty, about respect for elders, about appropriate interaction, and about the visibility of distress all affect what a young person will do in a waiting room, in a classroom, in a shop, and in a group of peers. The exposure plan has to be compatible with the young person's cultural context or it will be undone by it.

**The culture of the school system matters.** A school in which public behaviour is highly visible and where a young person's distress is noticed by everyone will present a different exposure problem from a school in which it is not.

## 12.2 The ethics of deliberately producing distress

The ethical analysis of exposure is unusually rich, and a student should be able to argue it.

**The core claim.** Deliberately inducing distress in a young person in order to remove distress is defensible only when four conditions are met: the disturbance is not needed to live a full life (that is, the fear is genuinely impairing); the person has consented to the specific procedure, with the capacity to withdraw; the intervention is expected to work, on the evidence, and the professional is competent to deliver it; and the distress is not being produced for the convenience of the practitioner or the institution.

**The consent condition.** Consent to a treatment in general is not consent to a specific exposure, and the consent must be renewed as the treatment proceeds, because the nature of the exposure changes as the hierarchy ascends. A young person who consented to sitting in the corridor may not have consented to a group of peers being assembled in front of them, and the difference matters.

**The capacity to withdraw.** A young person must be able to stop the exposure, and must be able to do so without the withdrawal being treated as a failure of treatment or as evidence about them. A practitioner who takes personally a young person's request to stop will find that they get more, not fewer, completed exposures, because the young person knows that the option is real.

**The proportionality condition.** The intensity of the exposure must be proportionate to the impairment. A young person with a mild school anxiety and a young person unable to leave the house are not receiving the same treatment, and the second case usually requires a more careful, more gradual, and more supported approach than the first.

**The non-maleficence condition.** The exposure must not produce harm. Where the feared outcome is possible, where the young person has a vulnerability that the exposure would activate, or where the exposure would exceed the young person's developmental capacity, the procedure must be modified or abandoned.

**The right to a second opinion.** A young person, or a family, who has serious concerns about an exposure programme should be able to obtain one, and the practitioner should be able to name a colleague who could provide it.

### 12.3 Specific ethical considerations with young people

**The parent's role in the decision.** Where the parents are the ones who are refusing the treatment on the young person's behalf, the ethical question is usually not about the parent but about what is at stake for them, and it is worth exploring what the parent's own fear or expectation is.

**Withdrawal in a school setting.** A young person who withdraws from an exposure in school needs the withdrawal to be handled in a way that does not create a public event, and the school needs a written plan for this in advance, because it will happen.

**Cultural and religious considerations.** Where the young person's family has a practice that the exposure programme would disrupt — a diet, a fasting period, a practice of avoidance that has religious significance, a gender-related expectation about contact with opposite-sex people — the programme must be designed around it. This is a practical matter as much as an ethical one, and the practitioner should ask.

**Documentation.** The exposure hierarchy, the young person's consent, the agreed stopping points, and the review points should be documented, because the programme is unusual enough that a careful record is a professional necessity, and because a record is the young person's protection as much as the practitioner's.

## 13. Key Terms

**Key Terms at a Glance**

- **Exposure** — The planned, systematic presentation of a feared stimulus, in conditions in which the feared outcome does not occur, for the purpose of producing new learning about the relationship between the stimulus and the outcome.
- **In vivo exposure** — Exposure conducted in the actual physical context in which the fear occurs; the default modality for most specific phobias with young people.
- **Imaginal exposure** — Exposure using constructed images, scenes, or narratives, used where the real stimulus is unavailable.
- **Interoceptive exposure** — The deliberate induction of feared bodily sensations, used with panic and somatic presentations.
- **Virtual reality exposure** — Exposure conducted in an immersive virtual environment, used where the real stimulus is dangerous, scarce, or expensive.
- **Exposure hierarchy** — A collaboratively constructed, individually specific, and graded list of feared situations with subjective distress ratings, ordered from most to least tolerable.
- **First-day design** — The practice of beginning treatment with a single, small, planned, and bounded exposure to the feared stimulus, chosen to succeed, before substantial assessment or homework.
- **The law of effect applied to fear** — The principle that avoidance is negatively reinforced by the relief it produces, and that the avoidance therefore maintains the fear.
- **Inhibitory learning** — The account of exposure as the learning that the feared outcome does not occur, which supersedes rather than erases the original learning.
- **CS–US association** — The learned association between the conditioned stimulus and the aversive unconditioned stimulus, the interruption of which is the aim of exposure.
- **Safety signal** — A stimulus that reliably accompanies the feared situation and thereby signals safety; its use is helpful in the early phase and must be faded.
- **Safety-seeking behaviour** — Behaviour that reduces the perceived danger at the cost of maintaining the fear; a primary target of exposure.
- **Avoidance** — The behaviour of escaping or postponing a feared situation, negatively reinforced by the relief produced; the principal maintaining factor in anxiety disorders.
- **Behavioural experiment** — A collaborative test of a specific prediction, designed so that the belief is genuinely at risk of disconfirmation.
- **Prediction–outcome discrepancy** — The comparison of the young person's expected outcome with the observed outcome; the mechanism by which the learning occurs.

## Key Terms at a Glance (continued)

- **Exposure protocol** — A manualised specification of the elements and rules of an exposure treatment, with defined sessions, homework, and review points.
- **Prolonged exposure** — A structured protocol for the treatment of post-traumatic stress disorder, with a focus on the emotional processing of the traumatic memory.
- **Exposure and response prevention** — The behavioural treatment of obsessive-compulsive disorder, combining exposure to the obsession with the prevention of the compulsion.
- **Grade of exposure** — The degree of difficulty assigned to a particular exposure, calibrated so that it is challenging but achievable.
- **Retrieval work** — Repeated re-exposure across time and contexts, designed to protect the learning against spontaneous recovery and relapse.
- **Modelling** — The demonstration of a behaviour by another person, through which the observer acquires or performs the behaviour.
- **Participant modelling** — A graded procedure in which the therapist models the feared behaviour and then guides the young person through it with progressively less assistance.
- **Co-participant modelling** — Modelling in which the model is a peer or a group member rather than the therapist.
- **Vicarious reinforcement** — The increase in the observer's performance of a behaviour following the observation of a model being reinforced for it.
- **Observational learning** — Bandura's account of learning through attention, retention, and reproduction, without direct reinforcement of the observer.
- **Behavioural rehearsal** — The graded practice of a behaviour in a low-risk setting, with feedback, before performance in the natural setting.
- **Instruction** — The explicit teaching of a target behaviour, its rationale, and often a script; the first of the four components of skills training.
- **Behavioural skills training** — A structured four-component method for teaching a specific interpersonal or self-management skill: instruction, modelling, rehearsal, and homework.
- **Homework** — The planned practice of a target behaviour in the natural setting between sessions; the generalisation step of skills training and of exposure.
- **Target behaviour** — The specific, observable behaviour that a treatment is intended to produce, defined in operationally countable terms.
- **Avoidance of the exposure** — The premature termination of an exposure, which is the commonest form of treatment failure and which is reinforced by the relief it produces.

**Key Terms at a Glance (continued)**

- **Agitated response** — A pattern in which distress escalates to a degree that the session cannot continue, requiring a lower dose, more modelling, and a slower grade.
- **Parent-delivered exposure** — Exposure in which the parent is coached to conduct the hierarchy, which generalises the learning into the family environment.
- **Parental accommodation** — Sustained parental modification of family routine and rules in response to the child's anxiety, which is now understood as a maintaining factor.
- **School refusal** — A pattern of persistent non-attendance at school that requires functional analysis before treatment, because at least four distinct maintaining patterns are recognised.
- **Relapse prevention** — The set of procedures designed to maintain gains after the end of treatment, including booster sessions, retrieval work, and written plans.
- **Booster session** — A planned follow-up session after the end of treatment, offered to consolidate gains and to address early signs of return.
- **Proportionality** — The ethical requirement that the intensity of an intervention be proportionate to the severity of the impairment it addresses.
- **Informed assent** — The young person's own agreement to a specific procedure, given with the capacity to decline and to withdraw.

## 14. Chapter Summary

Exposure is the most successful behavioural intervention in the history of the profession, and it emerged from a theoretical dispute whose resolution was methodological as much as theoretical. The psychoanalytic account held that a phobia was a symbol; the learning account held that it was an acquired and maintained fear. The comparative evidence showed that the treatment that followed from the learning account worked and the treatment that followed from the symbolic account did not, and the field took from this the lesson that a treatment which does not relieve the symptom does not work, whatever its theory.

The five principles of exposure were stated in this chapter: the feared stimulus must be encountered; the feared outcome must not occur; avoidance must be prevented; the exposure must be repeated; and the young person must do it themselves. Each was examined in relation to the developmental context, and the chapter developed the specific adaptations that follow from the cognitive capacity of the young person, the developmental gradient of the fear, the gradient of the young person's control over the exposure, the role of the parent, and the school context.

The varieties of exposure — in vivo, imaginal, interoceptive, and virtual — were described with their indications and limitations, and the hierarchy and the first-day design were set out in detail, because the details are what make the treatment safe. The rules of exposure practice were specified, and the single most important of them is the prevention of avoidance, since the premature termination of an exposure is the commonest treatment failure and is itself reinforced.

Modelling was described through Bandura's mechanisms of attention, retention, and reproduction, and its adaptation for young people was set out with the emphasis on credibility, multiple models, and the

demonstration of discrepancy between prediction and outcome. Behavioural rehearsal and behavioural skills training were described in their four components, and the chapter traced the components to their theoretical origins, making explicit that skills training is where the behavioural and the cognitive traditions are most completely integrated and that it does not deal with motivation, relationship, or developmental context.

The case of Tomas illustrated the separation of a referral question about defiance from a presenting problem of avoidance, the construction of a graded exposure with a planned check of the feared outcome, the work on the self-image belief, and the necessity of a school plan that included a decision not to pursue the punctuality target, since its pursuit would have provided a strong reinforcement for the avoidance.

The evidence is among the strongest in the literature for the specific phobias, for panic disorder, for social anxiety disorder, and for obsessive-compulsive disorder, and is substantial and growing for the anxiety disorders of childhood and adolescence. The component studies are more instructive than the outcome studies, and they identify repeated exposure, homework, the prediction–outcome check, and attention to predictions as the elements that make the difference.

The ethical analysis is the richest in the book, because the treatment deliberately produces distress. The conditions of defensibility are the necessity of the distress, the consent to the specific procedure, the expectation of benefit, and the absence of institutional convenience. The cultural analysis adds the point that some fears are collectively held and some fears are real, and that an exposure programme that confronts a real danger without a safety assessment is a serious ethical failure.

## 15. Review and Discussion Questions

**Review and Discussion Questions**

1. Describe the theoretical dispute between the psychoanalytic and the learning accounts of phobia, and state how it was resolved.
2. State the five principles of exposure and explain the rationale for each.
3. Distinguish in vivo, imaginal, interoceptive, and virtual exposure, and state the indication for each.
4. Explain the three rules governing the construction of an exposure hierarchy.
5. Describe the first-day design and state the three claims in its rationale.
6. State the ethical requirements that must accompany a first-day exposure.
7. State the core rules of exposure practice and explain the significance of each.
8. Explain what is meant by an inhibitory account of the learning in exposure.
9. Describe the "checking" of the feared outcome and explain why it is central to the modern protocol.
10. Describe the prevention of safety-seeking behaviour and explain why it is difficult.
11. Explain Bandura's three mechanisms of modelling, and describe participant modelling and co-participant modelling.
12. Describe the four components of behavioural skills training and explain why the order is fixed.
13. Explain how behavioural skills training integrates the behavioural and the cognitive traditions.
14. State the four adaptations of exposure that follow from the developmental status of the young person.
15. Explain the significance of the parent's anxiety in the treatment of a young person's anxiety.
16. State what is now understood about parental accommodation and what a practitioner should do about it.
17. Describe the four maintaining patterns in school refusal, and explain why a single treatment plan fails.
18. Describe the first-day design as applied to school refusal.
19. Distinguish the healthy response, the avoidance response, and the agitated response in an exposure session.
20. Describe the case of Tomas and explain the two features of it that generalise.
21. Summarise the status of the evidence for exposure with specific phobias, panic disorder, social anxiety disorder, and obsessive-compulsive disorder.
22. Summarise the component findings about repeated exposure, homework, checking the feared outcome, and the prediction–outcome comparison.

**Review and Discussion Questions (continued)**

23. State the four limitations of the exposure evidence base.
24. State the four conditions under which deliberately inducing distress in a young person is defensible.
25. Explain the two cultural considerations that may make an exposure plan inappropriate or require its modification.

## 16. Practice Activities

**Practice and Application**

### Activity 25.1 — Building a First-Day Exposure (75 minutes, individual)

Choose a young person you know or a case from placement who is avoiding something. Build the smallest possible first-day exposure: what it is, how long it lasts, who is present, what is said beforehand, what the young person is told they will feel, what the stopping point is, and what the young person does immediately afterwards. Then write the sentence you would say to the young person to introduce it. The purpose is to discover how hard it is to make the exposure small enough, and most students find that their first design is much larger than the one they end up writing.

### Activity 25.2 — The Prediction–Outcome Table (60 minutes, individual)

Take a fear of your own — a genuine one, however small — and complete ten rows of a table with the columns: situation, predicted outcome, predicted distress (0–100), actual outcome, actual distress, and the discrepancy. Do not complete the table from memory at the end; fill in each row immediately after the event. Then write what you would now believe if you were to design a similar table for a young person. The exercise demonstrates the mechanism, and it also demonstrates how much of the anticipatory dread is produced by the absence of a record.

### Activity 25.3 — Skills Training Rehearsal (90 minutes, small group, three roles)

In groups of three, one student plays a fourteen-year-old who is afraid of raising a problem in front of a teacher, one plays the teacher, and one plays the skills trainer. The trainer must run the four components — instruction, modelling, rehearsal, homework — on the target behaviour of asking a question in a lesson. Then swap roles so that each student plays the young person. The role of the young person is the instructive one, because it exposes the difference between a behaviour that has been rehearsed and a behaviour that has been modelled, and the difference between a young person who is coached and a young person who is instructed.

### Activity 25.4 — The Refusal and the Withdrawal (60 minutes, pairs, discussion)

In pairs, one student plays a parent who is convinced that their thirteen-year-old's refusal to attend school is a deliberate act of defiance and that the treatment should involve consequences, and the other plays the counsellor. The counsellor's task is to establish the maintaining contingencies without dismissing the parent's account, and to explain the parental accommodation literature without implying that the parent has been doing the wrong thing. Then reverse roles. The exercise is the best preparation in the book for the first family meeting in a school refusal case.

## 17. Annotated Reading Pathways

**For the treatment.** Read Wolpe (1958) for the origin and Bennett-Levy and colleagues (2016) for the modern protocol. The distance between the two is the history of the field in one comparison.

**For the evidence.** Read the meta-analyses of exposure with children and adolescents and read the component reviews on homework and on the prediction–outcome check. The component reviews are more useful clinically than the outcome reviews, because they tell you which parts of the protocol to protect when time is short.

**For the child-specific adaptations.** Read O'Connell (2009) in full. It is the most practically usable of the child-focused exposure texts and it addresses the first-day design, the school-based work, and the parental

role in a form that can be used directly.

**For the case conceptualisation.** Read the chapter on anxiety disorders in the child-focused clinical texts and read the school refusal literature, which contains the most useful functional analyses available in the applied literature.

**For the ethics.** Read the ethical guidelines for the behavioural approaches and the critical literature on exposure with minors, and read the material on parental accommodation, which has implications well beyond exposure therapy.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Exposure, Modeling, and Behavioral Skills Training** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is the treatment of avoidance, fear, and deficit through systematic desensitisation, observation, and rehearsal. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is functional analysis, learning history, contingencies, mastery, and measurable behaviour change. The mechanism to keep in view is how antecedents, consequences, skills, avoidance, and environmental design select and maintain behaviour. The characteristic professional risk is using control without assent, reinforcing compliance rather than wellbeing, or ignoring the meaning and function of behaviour. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in classrooms, homes, clinics, and other real environments where behaviour occurs, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or

school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Amara is fifteen and is seen in a family support service for repeated classroom escalation. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Amara's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Amara explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on functional analysis, learning history, contingencies, mastery, and measurable behaviour change. The first intervention is deliberately modest. Amara chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Amara has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is

redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Amara can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?

- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Exposure, Modeling, and Behavioral Skills Training

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Exposure, Modeling, and Behavioral Skills Training** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

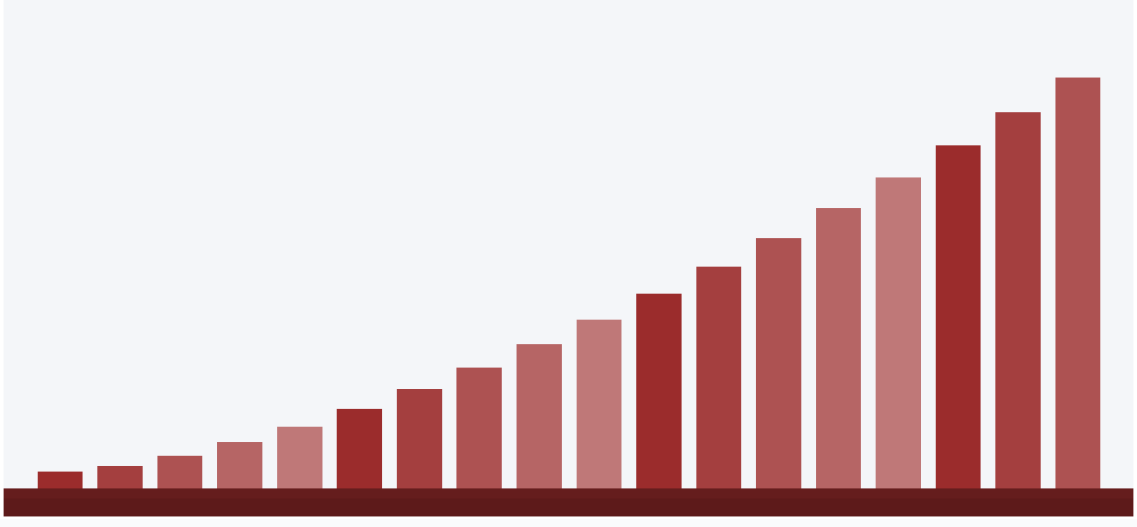
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Exposure, Modeling, and Behavioral Skills Training** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider

disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Exposure, Modeling, and Behavioral Skills Training**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Exposure, Modeling, and Behavioral Skills Training to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 26

# Operant Conditioning and Contingency Management

Reinforcement, schedules, and the deliberate shaping of behaviour in clinical and educational settings.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the principles of operant conditioning and the four contingencies, and apply them to a real situation.
- Describe the schedule of reinforcement typology and specify an appropriate schedule for a given clinical objective.
- Explain the difference between reinforcement schedules and token economies, and between token economies and behaviour contracts.
- Describe the full procedure of contingency management, from the specification of the target behaviour to the review of the plan.
- Explain the design and the use of behaviour contracts, and the legal and ethical limits of contracts with minors.
- Apply differential reinforcement, shaping, and fading to a clinical problem.
- Describe the management of a behaviour that is maintained by escape, and explain why punishment so often fails.
- Plan a contingency management intervention in a school or clinic, including the training of the adults who will carry it out.
- Critically evaluate the ethical and cultural dimensions of contingency management with young people.

## Chapter Overview

Operant conditioning is the branch of the behavioural tradition that deals with behaviour that operates on the environment. The vocabulary it has produced — reinforcement, punishment, extinction, shaping, fading, the schedules — is the shared language of most of applied behaviour analysis, most of the behavioural interventions for parents, and a good deal of school practice.

Its central insight is that behaviour is selected by its consequences. This is a claim about the environment rather than about the person, and it immediately suggests an intervention: if a behaviour is selected by a particular consequence, then changing the consequence changes the behaviour. Nothing about the behaviour itself needs to be inspected, interpreted, or treated.

The second insight is that the world in which the young person lives is a set of contingencies, and that these contingencies are usually maintained by adults who are not aware of them. The task of the practitioner is to map them, and the mapping frequently produces surprises: the behaviour that has caused the most concern is often the behaviour that is currently being reinforced, and the cooperation that has been requested is often the cooperation that is being withheld.

The third insight is more technical and more consequential than it first appears: the *schedule* on which a consequence is delivered determines the behaviour it produces, and the schedule is the variable that a great many real-world interventions get wrong. A token economy that pays for a behaviour once a week produces a very different young person from one that pays for it every time it occurs.

This chapter presents the operant principles in their technical form, the schedule typology in the detail in which it is actually used, and the three principal clinical applications — differential reinforcement and

shaping programmes, contingency management in a setting, and behaviour contracts — with the adaptations that young people require and the ethical constraints that apply to each.

# 1. Historical Context

## 1.1 Thorndike's cats and the puzzle box

The operant tradition begins in Thorndike's puzzle box, and the shape of the experimental work determined the shape of the clinical practice that followed. A cat that stepped on a pedal and escaped received, in Thorndike's design, a fish; a cat that failed to step received nothing, or received an unpleasant consequence. The cat learned over time, and the learning curve recorded the improvement.

Three features of this design are the direct ancestors of contemporary practice.

**The consequence is immediate.** The fish followed the pedal press within seconds. Everything in the modern operant literature about immediacy, and about the superiority of a small immediate consequence over a large delayed one, follows from this.

**The behaviour is measured by its frequency.** Thorndike timed the escape, and the recording of a rate of responding under specified conditions is the foundational technique of the whole applied tradition.

**The learning is inferred from the environment, not from the animal.** Thorndike's law of effect made no reference to intention, satisfaction as a felt state, or purpose. The cat did not act in order to escape; it escaped because acting in that way had paid off.

## 1.2 Skinner and the operant

Skinner's contribution was to make the analysis of behaviour into a research programme and then into a discipline. Three elements of his system are foundational for clinical work.

**The operant is defined by its effect.** An operant is a behaviour that operates on the environment and produces a consequence. This definition makes the behaviour itself, and not the mental state, the object of analysis, and it makes the analysis of a behaviour identical to the analysis of the environment in which it occurs.

**The three-term contingency.** The behaviour is always specified in relation to a **discriminative stimulus** (the occasion on which the behaviour occurs) and a **consequence**. The full relation is $S \rightarrow R \rightarrow S$ : the antecedent signals that a particular response will be reinforced; the response occurs; the consequence follows. Clinical work with young people is, in the most useful sense, the specification and the alteration of three-term contingencies.

**The principle of the functional analysis of behaviour** — that behaviour is selected by its consequences and is therefore analysable in terms of the contingencies that produce and maintain it.

Skinner also introduced the systematic experimental apparatus, the operant chamber, in which behaviour is measured across a series of carefully manipulated conditions. The chamber is not a piece of equipment that a counsellor uses; it is the model of the clinical environment, in which the practitioner arranges conditions, measures behaviour, and manipulates consequences deliberately.

## 1.3 The transition to the clinic

The application of operant principles to human problems began in the 1940s and 1950s in three settings: the treatment of chronic mental illness in institutional settings, where the modification of Token Economy systems in the late 1950s was a landmark; the modification of classroom behaviour; and the parent-training literature of the 1960s, which developed the operant account of oppositional behaviour into the most practically influential behavioural treatment in the child mental health field.

The institutional work produced the first systematic contingency management programmes and, with them, the first ethical controversy, because the early Token Economy systems in psychiatric wards used the withdrawal of privileges as a primary tool and applied them inconsistently. The controversy led to the field's most durable contribution: the analysis of contingencies, which shows that a pattern of escalating behaviour is very often maintained by the escape contingency that the pattern itself creates.

The parent-training literature was the most consequential for the present book. The demonstration that oppositional and conduct behaviour in young children is frequently maintained by a pattern of adult escalation — the more the child escalates, the more the adult withdraws the demand, so that the escalation is rewarded — was one of the most practically useful findings in the entire behavioural literature, and it is the foundation of the parent training evidence described in Chapter 33.

### 1.4 Behaviour analysis in the schools

The application of operant principles in the classroom has a long history, and the three main approaches are worth distinguishing because they are still in use and they are often confused.

**Token economy** — a system in which desired behaviour is reinforced with tokens exchangeable for backup reinforcers, applied to a group or a class.

**Contingency management** — a negotiated restructuring of the reinforcement structure of a setting, in which the specific consequences for specific behaviours are defined, taught, and reviewed.

**Behaviour contracting** — a written agreement, between a young person and an adult or an organisation, specifying what each will do, with specified consequences, and with the young person's signature.

All three are forms of the same underlying operation, and all three appear in Chapter 28, which addresses their use in schools and clinics specifically.

## 2. Reinforcement in Clinical Practice

### 2.1 The specification of a reinforcer

A reinforcer is a stimulus that, when made contingent on a behaviour, increases the future frequency of that behaviour. The definition is behavioural, which means that the question "is this a reinforcer?" is answered empirically and not by appeal to what ought to be motivating. A young person may value an item that the practitioner considers trivial, and may be unmoved by an item that the practitioner considers valuable, and the practitioner's opinion is irrelevant to the question.

The practical consequence is that reinforcers must be established. Three methods are used together.

**Establishment by observation.** The young person is observed in a setting in which the behaviour in question is already frequent, and the consequences that follow it are recorded. A young person who talks continuously in one class and is rewarded with attention there has a reinforcer available.

**Establishment by interview.** The young person is asked directly what they want, what they like, what they will work for, what they would spend their money on, what they would do for nothing. The answers are taken seriously even when they seem trivial.

**Establishment by testing.** A small amount of the candidate reinforcer is delivered, and the effect on the behaviour is observed. This is the only method that settles the question, and it is under-used.

### 2.2 The reinforcer survey

The **reinforcer survey** is a structured interview in which the young person, the parents, and the teachers are each asked the same set of questions about what the young person likes, wants, finds interesting, spends time on, and will work for. The three sets of answers are compared.

The comparison frequently produces the most useful single finding in a behavioural assessment. The young person wants X; the parents are willing to give Y; the teacher can actually deliver Z. Where these three sets do not intersect, the plan will not work, and the discovery is usually made only by asking all three.

### 2.3 Natural reinforcers and the motivational operations of the setting

The most durable plans use consequences that are already part of the young person's life. A child who enjoys drawing will work for drawing time far more reliably than for a token exchangeable for sweets, because the drawing does not have to be procured, scheduled, and administered, and because the value of it does not decline with repetition in the way that the value of an administered treat does.

This is the practical form of the account of **motivating operations** given in Chapter 23. The relevant question is not "what does this young person like?" but "what is scarce in this young person's current environment, and what would be abundant if it were provided?" Scarcity is what makes a stimulus reinforcing, and the practitioner's best move is often to provide something that is plentiful in the young person's world outside the clinic and scarce in the clinic.

### 2.4 Reinforcement and the young person's dignity

A systematic and sustained programme of reinforcement has an obvious dignity cost, and the practitioner should anticipate it. A young person who is rewarded for talking, and paid for it in tokens, may learn to talk for the tokens and may find the relationship with the practitioner humiliating.

Four practices reduce the cost without reducing the effectiveness.

**Reinforce the behaviour, not the person.** The young person earns the consequence for the behaviour, and the practitioner never indicates that the value of the young person is conditional.

**Use a range of reinforcers**, so that the interaction is not a transaction.

**Move towards natural consequences** as rapidly as possible, because natural consequences carry no dignity cost at all and generalise better.

**Fade the artificial system deliberately**, as a planned phase of the treatment, rather than abandoning it, which is experienced as a loss.

## 3. Schedules of Reinforcement

## 3.1 The four schedules

The schedule on which a reinforcer is delivered determines the behaviour it produces. Ferster and Skinner's typology is the standard description, and it remains the most useful single tool in the behavioural repertoire for matching a contingency to an objective.

**The fixed-ratio (FR) schedule** delivers the reinforcer after a fixed number of responses. FR 5 means the fifth response is reinforced, and then the count restarts. The characteristic pattern is a **post-reinforcement pause** followed by a high, steady rate: the pause after the reinforcement, then rapid responding until the next reinforcer. FR schedules produce high rates of response with brief pauses.

**The variable-ratio (VR) schedule** delivers the reinforcer after a variable number of responses, unpredictable to the organism. The characteristic pattern is a high, steady rate with no pauses, and this is the schedule that produces the most persistent behaviour. Gambling, and the use of slot machines, are the familiar examples, and the reason that a gambling schedule is so resistant to extinction is that the organism cannot distinguish a long run of losses from a schedule that has merely been quiet.

**The fixed-interval (FI) schedule** delivers the reinforcer for the first response after a fixed time period has elapsed. The characteristic pattern is a **scallop**: a pause after the reinforcement, then a gradually accelerating rate of response as the time approaches. FI schedules produce moderate rates with a distinctive temporal pattern, and they are the schedule that generates the "waiting until the last moment" behaviour that teachers and employers find so familiar.

**The variable-interval (VI) schedule** delivers the reinforcer for the first response after a variable time period. The characteristic pattern is a moderate, steady rate with no pauses, and this is the schedule that produces the most persistent and most stable behaviour of the four.

## 3.2 The schedule and the clinical objective

The typology is directly actionable, and the following table is the working summary that a student should carry into practice.

| Schedule | Behaviour produced | Clinical application |
|---|---|---|
| Fixed ratio | High rate, brief pause after reinforcement | Token systems, work-based reinforcement, discrete-trial programmes |
| Variable ratio | High, steady rate, highly persistent | Attendance in a group, completing a session, sustained effort tasks |
| Variable interval | Moderate, steady rate, most stable | Ongoing attention, monitoring, being available, homework checking |
| Fixed interval | Moderate rate, scalloped, "last minute" | Periodic check-ins, scheduled reviews, homework collection |

Two clinical consequences follow immediately. The first is that a *daily* reward for a behaviour that occurs many times per day is a fixed-ratio schedule and produces a pause after each reward, and a practitioner who has set a token economy with a small daily bonus will see the young person do the behaviour in a burst at the end of the day and not at all during it. The second is that a young person who is checked "every week" will do the work at the end of the week, and the fix is not more motivation but a shorter interval.

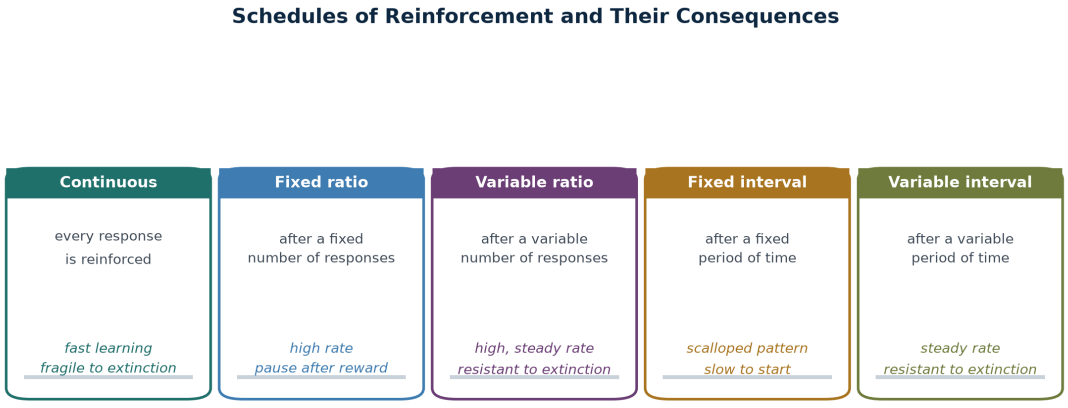


**Figure 26.15** The four schedules of reinforcement compared, showing the characteristic response patterns for fixed ratio, variable ratio, fixed interval, and variable interval schedules over time.

## 3.3 Reinforcement for acquisition and for maintenance

The schedule used during acquisition is not the schedule used during maintenance, and confusing the two is a common design error.

**Acquisition** is best served by a **continuous reinforcement** schedule: every instance of the behaviour is reinforced. The risk is that the behaviour becomes dependent on the reinforcement, and that the young person has not learned to perform it in the absence of the contingency.

**Maintenance** requires moving to a **thinning schedule**, in which the reinforcer is delivered less and less frequently, while the behaviour continues. The thinning schedule is the mechanism by which the behaviour becomes self-sustaining, and the rule of thumb is that the behaviour must be well established and consistent before thinning begins.

**The thinning rule.** The schedule should be thinned only after the behaviour has been established at a high and consistent rate, and the thinning should be gradual rather than abrupt. A behaviour that is thinned too early extinguishes, and the practitioner will misread the extinction as evidence that the behaviour is not under the young person's control.

**The transition to natural consequences.** The final stage is the transfer of the behaviour to the natural contingencies of the young's life, and the goal of the whole procedure is to reach it.

## 3.4 The extinction of over-learned behaviour

Extinction is not always the goal, and the practitioner should distinguish three situations.

**Extinction is appropriate** when the behaviour should stop and no alternative is required — the punching, the shouting, the out-of-seat behaviour that has no function other than its own continuation.

**Extinction is inappropriate** when the behaviour is positively reinforced. A young person who is being praised for elaborating on their day will not stop elaborating, and the attempt to extinguish the talking will produce a marked increase in the talking, which is the **extinction burst** and which the young person and the practitioner will both find alarming.

**Extinction is dangerous** when the behaviour is maintained by negative reinforcement. This is the case that most requires a functional analysis, and it is the subject of Section 5.

### 3.5 Differential reinforcement

**Differential reinforcement** is the reinforcement of one behaviour in a way that distinguishes it from another, and it is the technique of choice wherever a behaviour must reduce without the relationship deteriorating.

Three forms are used.

**Differential reinforcement of other behaviour (DRO)** — reinforcing any behaviour other than the target. It is the least specific form and is used when the target behaviour is dangerous and must be suppressed immediately, as in the case of self-injury.

**Differential reinforcement of an incompatible behaviour (DRI)** — reinforcing a behaviour that cannot be performed at the same time as the target. A young person who is learning to keep their hands occupied is reinforced for keeping their hands occupied, which is incompatible with hitting.

**Differential reinforcement of the target behaviour (DRT or DRA)** — reinforcing the target behaviour in the presence of the target, and reinforcing an alternative behaviour in its absence. This is the form that produces the most durable change, and it is the form most often required when a young person is working on a skill that is difficult in the situations in which it is most needed.

Differential reinforcement has a further advantage that matters in a clinical relationship: it is a way of reinforcing a young person *without* reinforcing the problem, and it therefore permits the practitioner to maintain a positive relationship with the young person at the same time as working on the problem behaviour.

## 4. Shaping and Fading in Clinical Use

### 4.1 Shaping revisited

The procedure was described in Chapter 23 and is repeated here in its clinical form, because the clinical details are what make it work.

**Specify the target behaviour precisely.** The written specification should describe what the young person will do, how the practitioner will know it has occurred, and what the target rate or duration is.

**Identify the starting approximation.** This should be a behaviour the young person already does, at least occasionally, and reliably enough to be reinforced.

**Order the approximations.** The ordering should reflect the difficulty, not the logical sequence. A common error is to order the approximations as the steps in the physical task, which ignores the fact that an earlier step may be the difficult one.

**Specify the reinforcer for each approximation**, and make it immediate.

**Define the advance criterion** — the number of consecutive correct performances at one approximation that justifies moving up. Without an advance criterion, the practitioner moves up when they feel ready, and the behaviour degrades.

**Define the step-back rule** — the conditions under which the practitioner returns to the previous approximation. This is the safeguard against the "too good to last" pattern in which a practitioner pushes a young person forward, the behaviour deteriorates, and the whole plan is abandoned.

**Define the maintenance criteria** — when the plan moves from shaping to thinning.

### 4.2 Prompting and fading

A prompt is any stimulus that assists the initiation or performance of a behaviour, and the fade plan is not optional. The hierarchy runs from the least intrusive to the most: a natural cue, a gesture, a verbal direction, a visual prompt, a modelling demonstration, a physical or hand-over-hand prompt, and finally a physical prompt.

**The fade plan must be written down before the prompt is introduced.** The fade is slower than the practitioner expects, and a plan that is not written down will be abandoned on the day.

**Fading is usually slower for a young person with a learning difficulty or an intellectual disability**, and the fade criteria should be adjusted before the plan begins rather than during it, because a young person whose behaviour deteriorates during a failed fade experiences it as failure and the relationship is damaged.

**Fading is faster in a natural setting than in a clinic**, and the transfer of the prompt from the clinic to the school is a specific problem, because the school staff will not have been trained in the prompt hierarchy.

### 4.3 Prompt dependence and its prevention

A behaviour that is maintained by a physical or a verbal prompt is not the behaviour the practitioner wanted, and the signs of prompt dependence are recognisable. The young person performs the behaviour only when prompted; the performance does not increase across sessions; and the behaviour disappears when the prompt is faded.

The prevention is procedural: fade systematically, confirm that the behaviour persists after the fade, and treat a failed fade as information about the approximation rather than as a failure of the young person.

## 5. Escape-Maintained Behaviour

Escape-maintained behaviour is the most important single category in applied practice, and the management of it is the point at which the operant analysis earns its keep.

### 5.1 The pattern

A young person who is asked to do something and who escalates — arguing, shouting, breaking something, running — is performing a behaviour that reliably terminates the demand. The escalation is not a failure of the behaviour; it is the behaviour working. The more severe the escalation, the faster the demand ends, and the more reliably the behaviour is reinforced.

The circularity is exact: the adult's response to the escalation is the maintaining contingency, and the adult's response is usually made in the belief that the escalation is the problem.

### 5.2 The clinical procedure

The management of escape-maintained behaviour proceeds in a defined order, and the order matters.

**Step 1: Establish that the behaviour is escape-maintained.** This requires data, and the data come from the ABC record, the incident log, and the interview. The practitioner looks for the pattern: escalation followed by withdrawal of the demand, and consistency of that pattern.

**Step 2: Identify the demand.** What is the specific demand, and what is the young person's response to it? A young person who cannot tolerate a demand they do not understand will escalate, and the escalation may be a request for help.

**Step 3: Plan the response.** The adult's response to the escalation is the treatment, and the plan must specify it in advance, in writing, and it must specify it for the whole team, because the plan fails if one adult in the corridor responds differently.

**Step 4: Teach an alternative.** A young person cannot be expected to comply with a demand that has no tolerable alternative. The alternative is usually a request for help, a break in a specified form, or a graded reduction in the demand, and it must be made available at the same time as the demand.

**Step 5: Fade.** The demand is increased gradually, and the alternative is faded as the compliance is established.

### 5.3 The differential reinforcement of compliance

**Differential reinforcement of compliance** — reinforcing compliance with a demand and ignoring escalation — is the core technique. It must be implemented with care, because the "ignoring" must be genuine: the practitioner must not look away, not speak, and not give any signal, because a signal of attention is a reinforcer.

The technique has a predictable course and the practitioner should prepare the young person for it. The behaviour increases in the first few sessions, because the young person is testing and the testing produces a burst. Then it declines, sometimes sharply, and the decline is a sign that the extinction is taking hold rather than a sign that the plan has failed.

### 5.4 Why punishment fails here

Punishment of escape-maintained behaviour fails systematically, and the reason is worth stating because it is the most practically useful thing in this section.

Punishing the escalation does not teach compliance; it teaches that the escalation has a cost, and the young person learns to escalate in a way that is less detectable or less costly. Meanwhile, the escape remains available and the avoidance behaviour, which is the behaviour that is actually maintaining the problem, is untouched. And because the practitioner has escalated the response, the young person has learned that adults in this situation become larger, which may increase the aggression in other settings.

The correct target is the avoidance, and the correct method is to make the demand tolerable and to reinforce the compliance, not to make the escalation expensive.

# 7. Contingency Management in Clinical Settings

## 7.1 The definition

**Contingency management** is the deliberate and negotiated restructuring of the reinforcement structure of a setting, in which the specific consequences for specific behaviours are defined in advance, taught to everyone involved, and reviewed at stated intervals. It is broader than a token economy, which is one technique within it, and broader than a behaviour contract, which is another.

The defining features of contingency management are that it is **specified** rather than improvised, that it is **negotiated** with the people whose behaviour it governs, that it is **transparent** — everyone knows the rules — and that it is **reviewed**, with a stated end point, rather than being left to run indefinitely.

## 7.2 The procedure

**Step 1: Specify the target behaviours.** In a clinical setting, a small number of clearly defined behaviours, chosen because their change matters. A common clinical specification is: attending sessions; completing a specified task; not using substances during the session; contacting the practitioner between sessions.

**Step 2: Specify the consequences.** For each target behaviour, the consequence that follows it and the consequence that follows its absence. Both directions must be specified, because a contingency that only defines rewards is not a contingency.

**Step 3: Identify the reinforcers.** By the survey method of Section 2, and by testing the candidates.

**Step 4: Specify the schedule.** The interval and ratio, and the thinning plan.

**Step 5: Specify the rules for the exceptions.** A contingency that does not specify what happens when the rules are broken cannot be administered, and the specification should cover illness, absence, crisis, and the days when the young person is not capable of complying.

**Step 6: Train the staff.** Every person who will deliver a consequence must know the rules, and the training should be a rehearsal rather than a briefing. This step is the one most often omitted and the one most responsible for the failure of contingency management programmes.

**Step 7: Review at stated intervals.** A contingency that is not reviewed becomes an unexamined routine, and unexamined routines drift.

**Step 8: Fade and terminate.** Every contingency management programme should have a planned end. The goal of a token economy is not a young person who needs tokens; it is a young person who no longer needs the system, and a system with no end point is a system that has become the plan.

### 7.3 Contingency management with a young person in difficulty

The context of a young person's life makes contingency management unusually delicate, for three reasons.

**The young person's environment is shared.** The school, the home, and the clinic are three environments with three sets of contingencies, and if the three do not align, the young person will select the environment with the most generous contingencies, which is usually neither the one that is best for them nor the one they live in.

**The stakes of the consequences are uneven.** A young person in a foster placement or in a residential setting may be subject to a set of consequences that were never negotiated, some of which are severe and some of which are applied inconsistently, and the practitioner who introduces a negotiated system into that environment may find that the negotiated system is the least powerful one in the young person's life.

**The consequences are often experienced as unjust.** A young person who is used to a system in which the rules change according to the mood of the adult will experience a transparent system as a novelty, and the novelty is usually welcome, and the welcome is itself useful data.

### 7.4 The negotiated alternative

The **negotiated alternative** is a technique developed in the family literature and adopted more widely than it deserves. In it, the young person is asked to propose what they would be willing to do in exchange for what they want, and the practitioner negotiates from the young person's proposal rather than from a preset offer.

The technique is powerful because it produces a commitment, and it is limited because the young person's proposal will usually be worse for the practitioner than a preset offer, and the pressure to accept it is difficult to resist. The balanced practice is to take the young person's proposal seriously, to state the constraints honestly, and to make the final agreement one that the practitioner could actually deliver. A young person who has negotiated a reward the clinic cannot provide has been set up to fail, and the failure will be attributed to the young person.

## 8. Behaviour Contracts

## 8.1 The structure

A **behaviour contract** is a written agreement specifying what each party will do, and the consequences of their doing or not doing it. The standard elements are: the parties; the specific behaviours promised by each party; the duration of the agreement; the specified consequences; the review date; and the signatures.

The feature that distinguishes a contract from a token economy is **reciprocity**: the adult also makes promises, and the consequences apply to the adult as well. A contract in which the young person promises to attend three sessions and the practitioner promises to be there at the agreed time, with a stated consequence if the practitioner is not, is a different instrument from one in which only the young person is bound.

Reciprocity also serves a clinical purpose. It converts the young person from the position of a subject of the system to the position of a participant in it, and the young person who has a say in the design of a contract is markedly more likely to be honest about it in the review.

## 8.2 Contracts with minors

A contract with a young person is an agreement and not a legal instrument, and this must be clear. A contract with a minor cannot be enforced in the way an employment contract can, and a practitioner who presents it as binding is misrepresenting its status.

Three limits should be observed.

**The consequences must be within the adult's power to deliver.** A consequence that depends on another authority — a school's attendance policy, a benefit agency, a court — is not a contractual consequence and should not be written as one.

**The contract must not contract for the removal of a young person's rights.** A contract that trades a young person's right to see a friend, or their right to privacy, or their right to complain about a staff member, for behaviour is an abuse of power regardless of how it is framed, and no behavioural formulation justifies it.

**The contract must be voluntary.** A young person who is required to sign a behaviour contract as a condition of continued attendance in a school or a service has not entered into an agreement.

## 8.3 The uses of a contract

Contracts are well suited to a young person who is older, who is able to understand the terms, and whose behaviour is a matter of a stable disagreement rather than of a clinical symptom. They are particularly useful in three situations.

**Ambivalence about treatment.** A young person who is ambivalent about therapy can be helped to commit to a defined and limited number of sessions through a contract, and the contract makes the commitment concrete and reviewable.

**Ambiguity about what is expected.** A young person who does not know what is expected of them cannot be held to it, and the contract specifies it.

**Conflict between a young person and a school.** A contract between a young person and a school, with the school also bound, can change the terms of an argument that has become entrenched.

Contracts are poorly suited to young children, to young people in acute crisis, and to situations in which the central difficulty is the young person's safety.

### 8.4 The review

Every contract must have a review, and the review is the part that most often does not happen. The review is a shared examination of what happened, and it is where the agreement is amended, extended, or ended. A contract reviewed only when it breaks down is not a contract; it is a set of threats.

## 9. Case Illustration: The Young Person Who Would Not Eat

**Presentation.** Ahmed is eleven and has been referred by his school because he has been refusing to eat in the dining hall, and he now eats a small amount at home before school. He is very thin, and his mother is frightened. The school has tried a variety of approaches, including a "healthy lunch club" for children who are not eating, and a reward chart for "eating a whole sandwich", and both have failed.

**The assessment.** The behavioural assessment establishes three things.

*The behaviour.* Ahmed does not eat in the dining hall. At home he eats, and he eats a restricted range. The mother reports that he eats pasta, rice, plain chicken, and nothing else, and that this has been the case for two years, and that it started after a year in which he was "sick" and "couldn't keep food down".

*The antecedents.* The observation in the dining hall is unremarkable in a way that is itself informative. Ahmed sits with a group of boys, he does not talk much, nobody is attending to him, and the food in front of him is disliked. There is no peer pressure, no coercion, and no obvious social consequence. He simply does not eat.

*The consequences.* When he does not eat, nothing happens. He leaves the dining hall, goes to the corridor, and is alone for twenty minutes, and he is not spoken to.

**The hypothesis.** The behaviour is maintained by the **avoidance of the dining hall**, and the avoidance is maintained by the relief of leaving, and — this is the crucial finding — the young person has no experience of what eating there would be like, because he has not done it for two years. The condition that the avoidance prevents is not "eating" but "eating in that room, with those people, with that food."

There is a second and more serious question, which the behavioural assessment raises and must not conceal. The restriction began after a period of illness in which he could not keep food down, and the behavioural account cannot say what that illness was, whether there was vomiting, whether there was fear of vomiting, or whether the restriction is now maintained by something that is not a contingency at all. The practitioner must not proceed with the behavioural plan until the medical history has been established, and the referral to the paediatric service must be made first, because a restrictive eating pattern in an eleven-year-old requires medical assessment before any behavioural intervention.

**The plan.** The plan has two stages, and the order matters.

*Stage one: the medical and the assessment of the eating disorder.* The paediatric assessment, the eating disorder screening, and the family work that supports it. The behavioural work is deferred.

*Stage two: the graded return to eating in the dining hall.* This is an exposure and a shaping programme together, and it uses the principles of Chapter 25.

The hierarchy is built with Ahmed, and it is built in the small dimensions rather than the large one. The steps are: sit in the dining hall for two minutes with a plate of food and leave; sit for five minutes; sit with one friend; have a drink; have a sandwich and leave; have a sandwich and stay for the whole lunch period.

The reinforcer for each step is time in the corridor with his friend afterwards, which the school can deliver and which the reinforcer survey confirms is what Ahmed values.

The shaping is at the level of a single sandwich, and the advance criterion for each step is three consecutive successes.

The **fading** is built in from the start. The school agrees that the "healthy lunch club" arrangement ends, and that Ahmed returns to the dining hall rather than being assigned to a separate space, because a separate space removes the very cue that is being treated. The school also agrees that the adults do not comment on his eating, do not encourage, do not praise, and do not remark when he does not eat. The comments that were intended as encouragement are, in the operant analysis, attention that is contingent on the behaviour, and the praise for "eating a whole sandwich" is positive reinforcement of a behaviour that is reinforced only in that setting and nowhere else, which is why the reward chart produced no durable change.

**The family work.** Ahmed's mother is asked to make two changes. She stops cooking around his restriction and begins to serve the same food for the family, without comment, without negotiation, and without a separate "safe" meal for him. And she stops the "try just a little bit" routine, which is the most common and least effective of the responses to a restricted eater, and which has the effect of making every meal a negotiation in which the food becomes the arena.

The mother's anxiety about this plan is substantial, and it should be, and the practitioner should treat it as the central clinical task rather than as a compliance issue. A mother who is frightened of her son's health is being asked to stop the thing that is currently reducing her anxiety, and the anxiety will find another outlet. The plan therefore includes a regular appointment with the mother for as long as it takes.

**The outcome.** Ahmed progresses through the hierarchy over approximately eleven weeks, with two relapses, one following an illness and one following a conflict at home. The restriction at home narrows over the same period, which is expected and which is a useful sign. His weight improves slowly. The paediatric service remains involved, and the multidisciplinary plan is reviewed monthly.

**The interpretation.** The case illustrates the discipline's central clinical discipline: the question was not how to make Ahmed eat but what his not eating was accomplishing, and the answer — the relief of leaving a room he was not ready to be in, maintained by a contingency nobody had designed — changed the intervention entirely. It also illustrates the discipline's central clinical danger: the behavioural analysis was elegant, and it was the wrong analysis, because the behaviour had a medical cause that the contingency analysis could not see. The practitioner who had proceeded directly to the graded exposure would have treated a young person's illness as a habit.

# 10. Evidence and Research Support

## 10.1 The status of the evidence

The evidence base for operant interventions is large, and it is strongest where the intervention is specified, the behaviour is operationally defined, and the outcome is measured. The most important evidence findings are as follows.

**Parent training based on operant principles has a strong evidence base** for oppositional behaviour, conduct disorder, and disruptive behaviour in the school setting, and this is among the most replicated findings in the child behavioural literature. The Cochrane reviews of parent training for conduct disorder

and oppositional behaviour report substantial and durable effects, and the findings are among the most robust in the entire child mental health evidence base.

**Token economies have strong evidence for institutional and educational settings**, particularly for the reduction of disruptive behaviour in classes of students with behavioural difficulties, and the effect sizes in the meta-analyses are large.

**Differential reinforcement has strong support** for the reduction of specific behaviours and for the teaching of alternatives, and it is a component of nearly every successful behavioural programme.

**Schedules of reinforcement have strong experimental support**, and the translation of the schedule findings into clinical practice is well established in the applied literature.

**Contingency management for substance use has some of the strongest effects in the entire psychological literature**, with effect sizes for the treatment of stimulant and opioid use that are larger than those for any other treatment for these conditions, and Chapter 47 develops the ethical and practical questions that the strength of these effects raises.

## 10.2 The evidence with young people specifically

Three findings are specifically relevant to this book.

**Parent-delivered contingency procedures outperform practitioner-delivered procedures** for the younger age range, in which the contingencies that matter are in the home and the parents are the only people who can change them.

**The fidelity of the implementation determines the outcome**, and the studies that measure fidelity and find it low report null results that reflect the implementation rather than the intervention.

**Contextual factors moderate the effect.** Parent training works better when the child has a comorbid condition, which is a counterintuitive and well-replicated finding that is best explained by the observation that the presence of more severe behaviour increases the parents' motivation and the salience of the training.

## 10.3 Limitations of the evidence

**The literature is dominated by young children and oppositional behaviour.** The evidence for contingency management with adolescents, particularly in outpatient settings, is thinner than the evidence with parents of young children, and the field's adolescent applications are more often extrapolated than demonstrated.

**The outcomes are almost always behavioural**, and the measures of the young person's own experience of the intervention, of the family's experience, and of the durability of the change in naturalistic settings are much less systematically reported. This is the gap that the 1993 revisions of the applied research criteria were directed at, and it is still not fully closed.

**Many of the studies are conducted in settings with distinctive features** — residential schools, specialist classrooms, hospital wards — and the generalisation to a general school or a general outpatient clinic is a real question.

**The allegiance effects are substantial.** Where the researcher is a member of the behavioural tradition, the effects are larger, and this pattern is one of the most consistent findings in the entire evidence base, described in Chapter 7.

# 11. Strengths and Limitations of Contingency Management

## 11.1 Strengths

**It is specified, teachable, and reproducible.** A contingency management programme can be written down, handed to a team, and implemented with fidelity, and this is not true of most psychotherapies.

**It addresses the environment rather than the person.** The intervention is directed at the contingencies, which are in the adult's gift, and this is a considerable advantage where the young person's internal states are not.

**It produces rapid, measurable change.** Contingency management is often the most rapidly effective intervention available for a specific behaviour, and rapid change is important for a young person who is demoralised by a long history of unsuccessful attempts.

**It preserves the relationship.** Differential reinforcement permits the practitioner to reinforce the young person while working on the problem, and this is a substantial advantage over approaches that require the practitioner to withhold attention.

**It is portable across settings**, and it can be implemented by parents, teachers, and ward staff, with training.

## 11.2 Limitations

**It requires resources and consistency.** The programme requires trained staff, a stable environment, and the sustained attention of a practitioner. In a service with high turnover and low continuity, the failure is a failure of implementation and will be misread as a failure of the approach.

**It can be experienced as coercive.** A young person who is being managed by a written system of rewards and consequences may experience it as the loss of personal agency, and in some cases the experience will be accurate. The ethical section addresses this directly.

**It addresses the behaviour and not the context that produced it.** A contingency programme that reduces a young person's offending behaviour while leaving the conditions that generated it untouched has solved a symptom, and the practitioner should be alert to the possibility of a displaced problem.

**It can create dependence on the system**, and the fade plan is not optional.

**It says nothing about the young person's inner life**, and a young person whose behaviour is maintained by shame, by self-hatred, or by a conviction of their own unworthiness will not be helped by a system that addresses the contingencies of the behaviour.

# 12. Cultural and Ethical Considerations

## 12.1 The reward and the market

The contingency management framework is often criticised for importing a market model into relationships, and the criticism has a real core. A young person who learns that affection, attention, and privilege are commodities that must be earned by performance has learned something that is not only false but corrosive, and the literature on the effects of reward-based parenting is the empirical counterpart of the moral objection.

Four principles follow for the practitioner.

**Never contract for what should not be traded.** Basic attention, genuine warmth, and access to help should not be contingent on performance. The practical form of this is that a practitioner must not withdraw attention or warmth as a consequence, and must not ration approval.

**Reinforce the behaviour, never compliance with the practitioner.** The distinction is subtle and important: reinforcing a young person's honest report, or their effort, or their self-regulation, is different from rewarding them for agreeing with the practitioner.

**Use natural consequences wherever possible.** A natural consequence carries no dignity cost and generalises better, and the progression from artificial to natural is a progression towards autonomy.

**Be aware that the system changes the relationship.** A young person who is being managed by a token system will behave differently in the sessions, and the practitioner should be honest with themselves about the fact that some of the improvement observed in session is contingent on the session.

## 12.2 Cultural considerations

**Reinforcers are cultural.** The reinforcer survey must be conducted in the young person's own frame of reference, and the practitioner must expect that the young person's values may differ from the family's, from the school's, and from the practitioner's. In a context where material rewards are scarce, a token may be a very powerful reinforcer; in a context where material rewards are abundant, it may be a very weak one, and the practitioner who has assumed otherwise will build a plan on a contingency that does not exist.

**The family's own systems of reward and sanction are already operating.** A family in which compliance is rewarded with togetherness and independence is rewarded with freedom operates a contingency system, and a clinic-based programme that runs counter to it will be defeated by it. The most useful clinical question is not "what reinforcer will work?" but "what does this family already reward, and how can the plan be built on that?"

**The honour and the stigma of the systems.** In many communities, a token economy or a written contract introduces a public record of the young person's behaviour that is experienced as a humiliation. Where the young person's peers can see the system, the design must protect the young person's dignity, and in some settings the system should be invisible to peers.

**The authority to set contingencies.** In some settings, the assumption that a professional has the standing to determine what a young person will be rewarded for is itself a cultural assumption, and the resistance it generates is rational and should be understood on its own terms.

## 12.3 Ethical requirements

**Informed assent and the right to withdraw.** A young person must be able to decline to participate in a contingency programme, and the consequences of declining must be stated in advance. A young person who is in a residential or a school setting where the programme determines some of their access must be able to decline without penalty.

**Proportionality.** The magnitude of the consequences must be proportionate to the situation. A young person in a residential setting should not have a disproportionately large stake in a system over behaviour that is trivial.

**The prohibition on contingent aversive procedures.** The contemporary practice does not use contingent aversive stimuli.

**The prohibition on the deprivation of a young person's rights.** No system may trade access to education, to healthcare, to food, to rest, to privacy, to advocacy, or to complaint for behaviour.

**Protection against the failure of the system.** A contingency programme that a young person cannot meet has failed, and the response to the failure must be an adjustment of the programme rather than an increase in the consequences. The principle should be stated to the young person in advance: if the plan is not working, the plan changes.

**Documentation and review.** The programme, the rules, the review points, and the outcomes should be documented, and the young person should be able to see the record.

## 13. Key Terms

### Key Terms at a Glance

- **Operant** — Behaviour that operates on the environment and is selected by its consequences; distinguished from the respondent, which is elicited by a stimulus.
- **Three-term contingency** — The relation in which a discriminative stimulus signals that a response will be reinforced, the response occurs, and a consequence follows.
- **Discriminative stimulus (S )** — The antecedent stimulus that signals that a particular response will be reinforced and that another will not.
- **Consequence (S )** — The event that follows a response and that determines the future probability of that response.
- **Reinforcer** — A stimulus that, when made contingent on a behaviour, increases the future frequency of that behaviour.
- **Reinforcement value** — The degree to which a stimulus is preferred, which determines the amount of behaviour that can be acquired and maintained by its delivery.
- **Motivating operation** — An event that establishes or abolishes the reinforcing effectiveness of a stimulus.
- **Natural reinforcer** — A consequence that is already part of the young person's environment, requiring no administration and generalising well.
- **Reinforcer survey** — A structured interview with the young person, the parents, and the teachers, each asked the same questions about what the young person values, for the purpose of identifying a usable reinforcer.
- **Fixed-ratio (FR) schedule** — Reinforcement delivered after a fixed number of responses; produces a high rate with a post-reinforcement pause.
- **Variable-ratio (VR) schedule** — Reinforcement delivered after a variable number of responses; produces a high, steady, and highly persistent rate with no pauses.
- **Fixed-interval (FI) schedule** — Reinforcement delivered for the first response after a fixed time period; produces a scalloped response pattern.
- **Variable-interval (VI) schedule** — Reinforcement delivered for the first response after a variable time period; produces a moderate, steady, and very stable rate.
- **Scallop** — The characteristic acceleration of responding across a fixed interval as the reinforcement time approaches.
- **Post-reinforcement pause** — The brief cessation of responding that follows a fixed-ratio reinforcement.

## Key Terms at a Glance (continued)

- **Continuous reinforcement** — Reinforcement of every instance of a behaviour; appropriate to acquisition and unmaintainable as a permanent arrangement.
- **Thinning schedule** — The gradual reduction in the frequency of reinforcement, used to transfer control from the schedule to the natural environment.
- **Shaping** — The systematic reinforcement of successive approximations to a target behaviour.
- **Advance criterion** — The specified number of consecutive correct performances required before moving to the next approximation.
- **Step-back rule** — The specified conditions under which the practitioner returns to a previously successful approximation.
- **Prompt** — A stimulus that assists the initiation or performance of a behaviour.
- **Prompt hierarchy** — The ordering of prompts from least to most intrusive: natural cue, gesture, verbal direction, visual prompt, modelling, hand-over-hand, physical.
- **Fading** — The systematic withdrawal of a prompt across successive trials, with reinforcement transferred to the unprompted behaviour.
- **Prompt dependence** — A state in which the behaviour occurs only when the prompt is delivered and does not persist when the prompt is faded.
- **Differential reinforcement of other behaviour (DRO)** — Reinforcement of any behaviour other than the target behaviour.
- **Differential reinforcement of an incompatible behaviour (DRI)** — Reinforcement of a behaviour that cannot be performed at the same time as the target behaviour.
- **Differential reinforcement of other behaviour and the target (DRT/DRA)** — Reinforcement of the target behaviour in the presence of the target stimulus and of an alternative in its absence.
- **Differential reinforcement of compliance (DRC)** — Reinforcement of compliance with a demand, combined with the extinction of escalation.
- **Extinction** — The discontinuation of reinforcement, producing a decline in the behaviour.
- **Extinction burst** — A temporary increase in the frequency or intensity of behaviour at the beginning of extinction.
- **Escape-maintained behaviour** — Behaviour that is maintained by the removal or postponement of a demand; the escalation is the behaviour working, not failing.
- **Contingency management** — The deliberate and negotiated restructuring of the reinforcement structure of a setting, with specified consequences, trained staff, and stated review points.

**Key Terms at a Glance (continued)**

- **Token economy** — A system in which desired behaviour is reinforced with tokens exchangeable for backup reinforcers.
- **Backup reinforcer** — The item or privilege for which tokens are exchanged.
- **Behaviour contract** — A written agreement specifying what each party will do and the consequences, with a review date and signatures.
- **Reciprocity in a contract** — The principle that the adult also makes promises and is also bound by the stated consequences.
- **Negotiated alternative** — A technique in which the young person proposes what they will do in exchange for what they want, and the agreement is negotiated from that proposal.
- **Contingency fading** — The planned and staged withdrawal of a contingency as the behaviour becomes self-sustaining.
- **Antecedent behaviour consequence (ABC) data** — The observational record of the sequence surrounding a behaviour, used to generate and refine functional hypotheses.
- **Dignity cost** — The interpersonal cost to the young person of being managed by a reward and consequence system.
- **Contingency management for substance use** — The application of reinforcement principles to the treatment of substance use disorders, with unusually large measured effects.
- **Fidelity of implementation** — The extent to which an intervention is delivered as designed, measured and reported alongside the outcome.

## 14. Chapter Summary

Operant conditioning is the branch of the behavioural tradition concerned with behaviour that operates on the environment, and its central claim is that behaviour is selected by its consequences. The claim is simultaneously the theory, the method, and the clinical proposition: if a behaviour is selected by a particular consequence, then changing the consequence changes the behaviour, and nothing about the behaviour itself needs to be interpreted in order to intervene.

The chapter traced the lineage from Thorndike's puzzle box, through Skinner's three-term contingency and functional analysis, into the ward-based token economies of the 1950s, the parent training literature, and the classroom applications. The specification of a reinforcer was treated as a clinical task requiring three methods — observation, interview, and testing — and the reinforcer survey was presented as the most economical way of finding a usable reinforcer, with the important observation that the young person's, the parents', and the school's answers frequently do not intersect, and that the failure of the plan is usually determined at that intersection.

The schedule typology was presented in the detail in which it is used, with the characteristic response patterns of the four schedules and the clinical objectives for which each is appropriate, and the two practical consequences were drawn out: that a small daily bonus is a fixed-ratio schedule and produces end-of-day bursts rather than continuous performance, and that a young person checked weekly will work at the end of

the week. The distinction between acquisition and maintenance schedules was developed, with the thinning rule and the transition to natural consequences, and the three forms of differential reinforcement were set out with the clinical argument for differential reinforcement of compliance, which is the technique that permits a practitioner to work on a problem behaviour while maintaining a positive relationship.

The management of escape-maintained behaviour was treated at length, on the grounds that it is the most practically important single category in applied practice. The circularity was described — the adult's response to the escalation is the maintaining contingency — and the five-step procedure was set out, and the systematic failure of punishment in this case was explained rather than merely reported: punishment teaches the young person that adults become larger, leaves the avoidance untouched, and does not teach compliance.

Contingency management was defined as the negotiated restructuring of a setting's reinforcement structure, and its eight-step procedure was specified, with the training of staff identified as the step most often omitted and most often responsible for programme failure. Behaviour contracts were described with the principle of reciprocity, and the three limits that apply to contracts with minors were stated: that the consequences must be within the adult's power to deliver, that no contract may trade a young person's rights, and that the contract must be genuinely voluntary.

The case of Ahmed illustrated the discipline's central discipline and its central danger. The functional analysis of his refusal to eat was elegant, and it was wrong, because the restriction had begun with an unexplained illness and the contingency analysis could not see it. The multi-disciplinary sequence, the medical assessment preceding the behavioural work, the graded hierarchy, the elimination of the "healthy lunch club" arrangement, the removal of the attention that the adults believed was encouraging, and the mother's anxiety as the true clinical task, are all described in the case.

The evidence is strong for parent training, for token economies in educational settings, for differential reinforcement, and above all for contingency management in substance use. The limitations are the dominance of the younger age range and of oppositional behaviour, the predominance of behavioural over experiential outcomes, the dependence on distinctive settings, and the substantial allegiance effects.

The ethical analysis addresses the market objection to reward-based practice seriously and derives four principles from it: never contract for what should not be traded, reinforce the behaviour rather than the practitioner's preferences, prefer natural consequences, and be honest about the effect of the system on the relationship. The cultural analysis addresses the cultural specificity of reinforcers, the family's existing systems of reward, the public humiliation that a visible system can produce, and the question of the professional's standing to set contingencies. The ethical requirements are listed in full, and the principle that a programme a young person cannot meet is a programme that must change rather than a young person who must be punished closes the section.

## 15. Review and Discussion Questions

**Review and Discussion Questions**

1. State the three-term contingency and explain the role of each term.
2. Explain how the operant principle differs from the respondent principle, and give a clinical example of each.
3. Describe the three methods for establishing the reinforcing value of a stimulus, and explain why testing is the only decisive one.
4. Explain what a reinforcer survey is, and explain why the three sets of answers frequently fail to intersect.
5. State the four schedules of reinforcement and the response pattern characteristic of each.
6. Explain the post-reinforcement pause and the scallop, and state the clinical setting in which each is observed.
7. Explain why a small daily reward produces a burst of behaviour at the end of the day rather than continuous performance.
8. Distinguish the acquisition schedule from the maintenance schedule, and state the thinning rule.
9. Explain what happens when extinction is applied to a positively reinforced behaviour, and state the term for the temporary increase.
10. Distinguish differential reinforcement of other behaviour, of an incompatible behaviour, and of the target behaviour, and give a use for each.
11. State the six components of a shaping plan.
12. Explain what prompt dependence is, state the prompt hierarchy, and describe the fade plan.
13. Explain why the fade should be slower for a young person with a learning difficulty, and why the fade criteria should be set beforehand.
14. Describe the escalating pattern of escape-maintained behaviour, and explain the role of the adult's response in it.
15. State the five steps of the clinical procedure for escape-maintained behaviour.
16. Explain the predicted course of differential reinforcement of compliance, and why the practitioner should prepare the young person for it.
17. Explain systematically why punishment fails with escape-maintained behaviour.
18. State the eight steps of contingency management and identify the step most often omitted.
19. Explain the negotiated alternative and describe the balance a practitioner must strike in using it.
20. Describe the structure of a behaviour contract and explain the significance of reciprocity.
21. State the three limits that apply to a behaviour contract with a minor.

**Review and Discussion Questions (continued)**

22. State three circumstances in which a behaviour contract is appropriate and three in which it is not.
23. Describe the case of Ahmed and state both the methodological lesson and the clinical danger it illustrates.
24. Summarise the status of the evidence for parent training, token economies, differential reinforcement, and contingency management for substance use.
25. State the four ethical requirements that follow from the market objection to reward-based practice.
26. Explain the significance of the principle that a programme a young person cannot meet is a programme that must change.

## 16. Practice Activities

**Practice and Application**

### Activity 26.1 — The Schedule Audit (75 minutes, individual)

Take a real behaviour in a placement or in your own life and identify the actual schedule on which its consequences are delivered. Work out the fixed or variable ratio or interval, the typical magnitude of the consequence, and the delay between the behaviour and the consequence. Then redesign the schedule to produce the behaviour you actually want, and write down what the young person or other person would experience as different. The exercise teaches that most real-world problems with contingency management are problems with the schedule rather than with the reinforcer.

### Activity 26.2 — Reinforcer Survey with Triangulation (90 minutes, field-based)

Conduct a short reinforcer survey with a young person, a parent, and a teacher, using the same ten questions for each. Tabulate the three answers and identify the intersection and the divergences. Then test one candidate reinforcer by delivering it contingent on a specific behaviour and observing what happens. Most students find that the intersection is smaller than they expected, and that the divergences are the most informative part of the exercise.

### Activity 26.3 — Escape-Maintained Analysis (90 minutes, small group)

In groups of three, take a real behaviour that is described as "non-compliance" or "defiance" in a placement. Map the escalating sequence in detail: what does the adult say, what does the young person do, what does the adult do next, and what does the young person do then. Identify the point at which the demand is withdrawn and the consequence that produces. Then write the five-step plan for the case, with the differential reinforcement of compliance and the alternative behaviour specified. The most common finding is that the escalation is a well-rehearsed and effective request for help.

### Activity 26.4 — Writing a Behaviour Contract (75 minutes, individual)

Draft a behaviour contract for a realistic situation with a young person, with the adult also bound by specific promises. Specify the review date, the exceptions, and the consequences of each party's failure to comply. Then mark the draft, and identify the two places in it where you have contracted for something that should not be traded, and rewrite them. The second half of the exercise is the one that matters, and most drafts fail it in at least one place.

### Activity 26.5 — The Fade Plan (60 minutes, individual)

Take a prompting procedure you have used or observed and write a full fade plan: the prompt hierarchy from least to most intrusive, the number of trials at each level, the advance criterion, the step-back rule, and the schedule for the transfer of the prompt from the clinic to a school or home setting. Then write what you would do if the behaviour deteriorated at the third level. The transfer step is the one that most hand-written plans omit and the one that most often causes the treatment to fail.

## 17. Annotated Reading Pathways

**For the principles.** Read Skinner (1938) and then the Ferster and Skinner (1957) schedules volume in excerpt, and read the Milner (1953) laboratory chapters on reinforcement and extinction. The laboratory texts are worth the effort, because the clinical vocabulary was built in them and a student who has read them will find the clinical literature much easier.

**For the clinical craft.** Read the parent training literature, which is the most practically useful behavioural literature for work with young people, and read the parent guides that accompany it. Then read the applied texts on differential reinforcement, which contain the practical detail the theory does not.

**For the escape-maintained pattern.** Read the classic functional analysis of oppositional behaviour with a child and family, and then read the critical literature on the behavioural perspective with families, which is where the discipline's most serious self-criticism is to be found.

**For the evidence.** Read the Cochrane reviews of parent training and the meta-analyses of token economies in educational settings, and read the contingency management literature in substance use, which is the most methodologically mature part of the applied evidence base.

**For the ethics.** Read the ethical guidelines for the behavioural approaches and the literature on reward-based parenting, and read the critical accounts of the token economy in institutional settings. The historical material is the best preparation for the consent and documentation work in Part VIII.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Operant Conditioning and Contingency Management** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is reinforcement, schedules, and the deliberate shaping of behaviour in clinical and educational settings. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is functional analysis, learning history, contingencies, mastery, and measurable behaviour change. The mechanism to keep in view is how antecedents, consequences, skills, avoidance, and environmental design select and maintain behaviour. The characteristic professional risk is using control without assent, reinforcing compliance rather than wellbeing, or ignoring the meaning and function of behaviour. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in classrooms, homes, clinics, and other real environments where behaviour occurs, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning,

language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Jonas is fifteen and is seen in an integrated school and health team for difficulty trusting adults after several service changes. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Jonas's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Jonas explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on functional analysis, learning history, contingencies, mastery, and measurable behaviour change. The first intervention is deliberately modest. Jonas chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The

practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Jonas has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Jonas can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.

- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Operant Conditioning and Contingency Management

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Operant Conditioning and Contingency Management** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

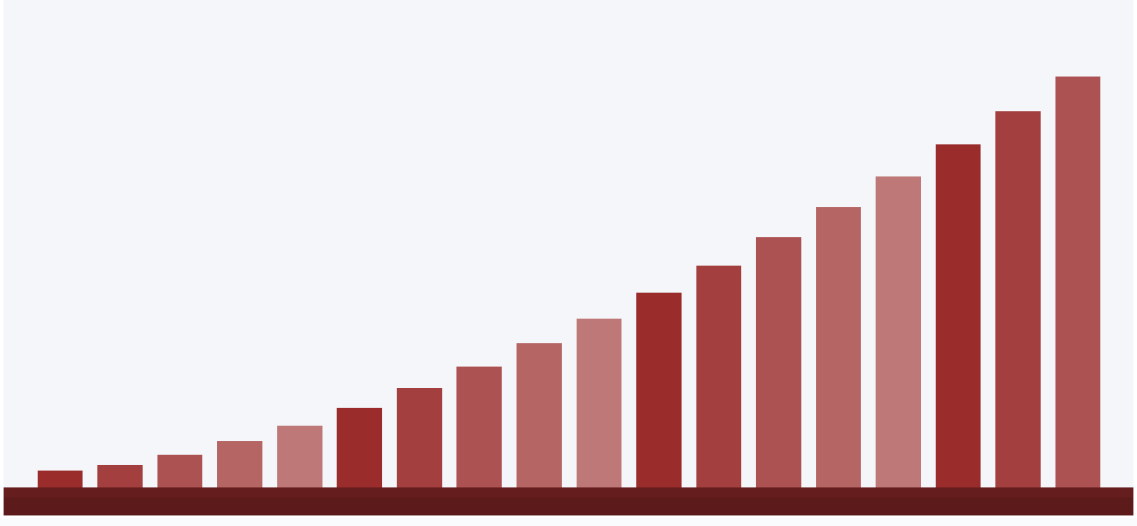
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Operant Conditioning and Contingency Management** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary

language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Operant Conditioning and Contingency Management**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Operant Conditioning and Contingency Management to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 27

# Behavioral Activation and Activity Scheduling

The behavioural treatment of depression and withdrawal in adolescents.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the origins of behavioural activation in the treatment of depression, and state the theory of depression it is based on.
- Describe the three components of behavioural activation, and explain the mechanism of change each involves.
- Describe the treatment rationale and the course of behavioural activation with an adolescent.
- Explain the relationship between behavioural activation and the cognitive model, and between behavioural activation and the behavioural principles of Chapter 23.
- Apply activity monitoring and activity scheduling to a case of adolescent depression and withdrawal.
- Describe the evidence for behavioural activation with young people, and evaluate its limitations.
- Explain the adaptations required for young people, including the specific modifications for developmental level and for the comorbidity of anxiety.
- Critically evaluate the cultural and ethical dimensions of behavioural activation with young people.

## Chapter Overview

The cognitive revolution gave depression a theory of mind. Behavioural activation gave it a theory of action, and the two theories turned out to be compatible in a way that was not obvious at the time.

The behaviour therapy tradition had observed since the 1930s that the defining features of depression are not attributions and not beliefs but **withdrawal**: the reduction of activity, of engagement, of contact, and of reward. People who are depressed do not think differently about the world so much as they do *fewer things*, and the reduction in activity produces a reduction in reward, and the reduction in reward produces a further reduction in activity. The account is a behavioural account of a cyclical process, and it makes a prediction that the cognitive account did not: that interrupting the cycle would produce improvement, and that the improvement would precede rather than follow the change in thinking.

The intervention follows from the account. Depression is maintained by a deficit of rewarding activity and by the avoidance of situations that have been associated with non-reward. The treatment therefore consists of identifying the rewarding activities that the person has stopped, scheduling them, and doing them — and, where the activities have been stopped because they have become unrewarding, restructuring them so that they are rewarding again.

For adolescents, the case for behavioural activation is unusually strong, for reasons that are developmental. The adolescent's primary developmental task is the construction of a social identity through competence and connection, and withdrawal is directly opposed to that task. The adolescent with depression is not only distressed; the depression is interfering with the very process by which distress would ordinarily be resolved. The treatment that re-engages the adolescent in activity is a treatment that works on the depression and on the development at the same time, and this is one of the clearest cases in the book of a theory-driven intervention that addresses a developmental principle as well as a symptom.

This chapter presents the theory, the procedure, the modifications for young people, the evidence, and the case illustration.

# 1. Historical Context

## 1.1 The behaviour therapy tradition and depression

The first wave of behaviour therapy approached depression through the classical conditioning literature, and the account was of depression as a learned helplessness response to uncontrollable aversive events. Seligman's work on learned helplessness was the most influential formulation, and it drew on the animal literature on exposure to uncontrollable shock, in which the animal's failure to escape is learned and generalised to situations in which escape is possible.

The treatment implication was a form of exposure: the deliberate restoration of control. Seligman and colleagues developed what became known as the **control therapy** or the **mastery** approach, in which the patient is given tasks of graded difficulty whose successful completion demonstrates that outcomes are contingent on behaviour.

This work was important and it was largely eclipsed. The reason is partly historical, because the cognitive revolution captured the field, and partly conceptual, because the learned helplessness account of depression is a theory of the acquisition of a deficit and says little about how the deficit is maintained, which is the question that most depressed patients present.

## 1.2 The activity record

The most important antecedent to behavioural activation was Jacobson's work in the 1930s, and specifically the **activity record**: a daily log in which the patient recorded, in hourly units, the activities of the day and, for each, a rating of the degree of pleasure and of the degree of self-mastery achieved.

The activity record was developed for a purpose that the field has since forgotten. Jacobson used it to demonstrate that the depressed patient over-estimates the unpleasantness and under-estimates the pleasure of their activities, and that the discrepancy between the patient's report and the actual experience is itself a maintaining factor: the patient avoids the activity on the basis of an expectation that the activity is unpleasant, and the avoidance prevents the disconfirming experience. In this respect, the activity record was the first treatment technology to target a belief through behavioural data rather than through argument, and the discrepancy it measured is the ancestor of the modern behavioural activation rationale.

## 1.3 The cognitive revolution and the divergence

The cognitive model of depression, developed from Beck's work in the 1960s, proposed that depression is maintained by a specific pattern of negative automatic thoughts, by negative core beliefs, and by the cognitive triad. It produced an effective treatment, and for two decades cognitive therapy was the dominant approach.

The divergence between the two traditions was sharp in the 1970s and softened in the 1990s, and the softening came from a direction nobody expected: from the recognition, inside the cognitive tradition, that behavioural activation was effective and that its effect on mood was more rapid than that of the cognitive interventions. The treatment produced a substantial improvement in mood in the first few sessions, before any cognitive work had been done, and this was a striking finding because the cognitive model had predicted that the cognitive work should come first.

The resolution was the observation that the cognitive and the behavioural interventions address the same process at different points in the cycle, and that the behavioural intervention acts upstream, on the

behavioural withdrawal that generates the negative thoughts, and the cognitive intervention acts on the content of the thoughts. The two are complementary, and the combination — which is now the most common form of the treatment — is described in Chapter 16 and Chapter 17.

### 1.4 Behavioural activation as a distinct treatment

The 1970s and 1980s saw the development of behavioural activation as a treatment in its own right, most influentially by Jacobson and colleagues, and later by the group associated with the New Haven school, who produced the treatment manual and the outcome studies.

The rationale was stated in a form that has become the standard statement of the treatment:

> *Depression is a disorder of behaviour in which the person has withdrawn from rewarding activities, and the withdrawal is maintained by the avoidance of situations in which the person has experienced non-reward and by the loss of the reinforcing consequences of activity. The treatment consists of the identification of activities that the person finds rewarding, the scheduling of those activities, and the performance of them, together with the reduction of avoidance and the mastery of necessary tasks.*

Two features of this rationale are worth emphasising, because they distinguish behavioural activation from everything else in the book.

**It predicts the sequence of change.** Mood improves before cognition changes. This is a testable and unusual prediction, and it has been supported.

**It explains why the depression persists even when the person "knows" better.** The person with depression has usually tried to think their way out of it and failed, because the withdrawal continues, and the withdrawal is what maintains the negative thoughts.

## 2. The Theory

### 2.1 The behavioural model of depression

The behavioural model holds that depression is not primarily a disorder of mood with a disorder of thought attached. It is a **disorder of behaviour** in which four processes operate together.

**The reduction of reinforcing activity.** The person stops doing the things that are rewarding. The reasons are a lack of energy, an absence of expectation that the activity will be rewarding, and the withdrawal itself.

**The increase in aversive activity.** The person substitutes activities that are aversive or numbing: rumination, worry, self-criticism, substance use, sleep, screen time, and overeating. These activities are frequently more immediately reinforcing than the alternatives, which is why the depression is so difficult to escape by intention.

**The avoidance of situations associated with non-reward.** The person avoids situations in which they have experienced rejection, failure, or a lack of recognition. The avoidance prevents the corrective experience.

**The disruption of the circadian and the physiological systems.** Sleep, appetite, activity, and light exposure become irregular, and the irregularity is itself a maintaining factor.

The model is a cycle rather than a list, and the cycle is the treatment's target: the withdrawal reduces the reward, the reduced reward increases the withdrawal, and the increasing withdrawal increases the avoidance, which further reduces the reward.

### 2.2 The role of the cognition

The behavioural model does not exclude cognition; it locates it. Cognition enters at three points.

**As an anticipation.** The person does not undertake an activity because they expect no reward from it. The expectation is the mechanism of the avoidance, and it is directly testable against the actual outcome.

**As an attribution.** The person attributes outcomes to global and stable causes — "I never get anything right", "nothing ever works out for me" — and the attribution generalises from a specific event to the whole of the person's life.

**As a self-evaluation.** The person evaluates the self through the activities undertaken and the results obtained, so that the reduction in activity reduces the number of occasions on which the self can be evaluated positively.

The behavioural approach to each of these is the same: change the activity, and the cognition follows. This is why behavioural activation can be delivered without cognitive disputation, and why it is often the preferred treatment for a young person who is not ready to examine his own thoughts.

### 2.3 The reinforcing value of activity

The treatment rests on an assumption that is worth examining: that activity is reinforcing, and that the reinforcing value of an activity is a function of its *immediacy* and its *certainty*.

**Immediacy.** A consequence that is delayed is less reinforcing, and this is why many of the activities that a depressed adolescent gives up are those with delayed reward — studying for an exam, applying for a job, learning an instrument, writing to a friend. The behavioural approach is to restructure the activity so that the reward is immediate: study for twenty minutes and then do something enjoyable, rather than studying for three hours in the hope of a result in June.

**Certainty.** An activity whose outcome is uncertain is less reinforcing than one whose outcome is predictable, and this is the rationale for the graded task in mastery work: a task with a predictable and achievable outcome provides a reliable small reward at a time when the young person needs reliable small rewards.

**Magnitude.** A large activity is more rewarding when it is done, but it is much less likely to be done, and in a depressed adolescent the probability of undertaking matters more than the magnitude of the reward.

**Social contact.** Almost all activities that maintain well-being in adolescence are social, and the social component is usually the component that has been lost. The activity schedule must therefore be a schedule of *contact* as much as a schedule of tasks.

## 3. The Three Components

### 3.1 Activity monitoring

**Activity monitoring** is the daily record in which the young person logs their activities, together with a rating of the pleasure and of the mastery associated with each. The Jacobsonian version used hourly units across the day; the modern versions use a simpler daily or twice-daily log, and the simplification is a developmental adaptation.

The purposes of the monitoring are four.

**To establish the baseline.** The clinician needs to know what the young person's days actually contain, and the answer is frequently surprising. A young person who presents as "doing nothing" has days that are full — of sleeping, of scrolling, of eating, of avoidance, of small tasks that occupy the time without occupying the person.

**To make the discrepancy visible.** The monitoring shows, on the page, the difference between the activity and the predicted quality of the activity. The young person can see the entries for the Saturday when they "did nothing" and can see the rating of pleasure recorded against it.

**To establish the pattern.** A weekly graph of activity levels against mood levels shows the relationship, and it usually shows it clearly.

**To provide the data for the schedule.** The activities with the highest pleasure ratings and the lowest mood ratings are the candidates for the schedule, and this is why the monitoring precedes the scheduling.

**The practical problem with monitoring is compliance**, and the clinician should expect that a depressed adolescent will not complete the log. Three responses are useful. The log should be short. The clinician should complete the first day with the young person, sitting with them and logging their day. And the log should be reviewed in the session, not collected and left.

## 3.2 Activity scheduling

**Activity scheduling** is the specification of what the young person will do, when, and with whom, and it is the active component of the treatment. The specification should be written in three columns: the activity, the day and time, and the person involved.

Four principles govern the schedule.

**Schedule activities that are rewarding, in the sense of the section above.** The activity should be selected on the basis of the pleasure ratings from the monitoring, and it should be one the young person has actually enjoyed at some point, not an activity chosen by the clinician because it would be good for them.

**Schedule mastery activities alongside pleasure activities.** This is the Jacobson and colleagues' contribution and it is the part most often omitted. The depressed adolescent's problem is not only that they do nothing; it is that they have stopped doing the difficult things, and the difficult things are where the self-evaluation is generated. The mastery activity is specified in graded steps, with the smallest step achievable.

**Schedule social contact.** Because the social element is the one that has been lost and the one that most distinguishes the adolescent depression from the adult depression, the schedule must include contact with other people, and the contact must be specified in terms of the people and the duration.

**Schedule into the difficult slots.** The schedule is built around the times in the week when the withdrawal is worst, and not around the times when the young person is already functioning.

## 3.3 Activity monitoring and the graded task

**Graded task assignment (GTA)** is the third component, and it is the one most associated with behavioural activation and with the treatment of depression in young people.

The procedure has two halves. In the first, the young person and the clinician construct a **task hierarchy** of activities, from those that are currently impossible to those that are currently easy, with the activities graded by difficulty, and with the steps specified in the units in which they would actually be done. A typical hierarchy for an adolescent who has withdrawn from school might run: get out of bed before my mother calls me; get dressed; have breakfast; sit at the table with my phone; walk to the end of the road; walk to the shop; go to the college café; go to a lesson.

In the second, the young person works up the hierarchy, completing one or two steps beyond their current position, and each completed step is recorded and acknowledged, and the acknowledgement is the reinforcement.

The hierarchy is constructed collaboratively and is based on the young person's own specification, and the clinician's role is largely to break the steps down into a fine enough grain. The most common clinical problem is a hierarchy whose first steps are too large, and the fix is always the same: subdivide further, until the first step is something the young person is confident they could do today.

**The rules of graded task assignment** that the evidence supports are specific. The tasks should be achievable but not trivial. The young person should choose the tasks, from a list the clinician has helped to construct. The hierarchy should be reviewed and adjusted weekly. Completion should be recorded and acknowledged immediately. The tasks should be broken down until the first step is clearly achievable, and no exceptions to this rule should be made.

### 3.4 The session structure

The typical behavioural activation session is short, structured, and practical.

**Review of the monitoring.** What did the young person do, and what was the mood? The review is brief and the clinician is careful not to moralise about the content of the log.

**The discrepancy.** The comparison between the predicted and the actual quality of the activities. The clinician's posture is curious rather than triumphant.

**The schedule.** The activities for the coming week are agreed and written down, and the young person takes the schedule away, and the schedule is the homework.

**The graded task.** One step of the hierarchy is added, and the step is small.

**The problem-solving of obstacles.** What is going to make this hard, and what will you do? The question is asked in advance, because it is much easier to solve the problem on Wednesday than in the session on Friday.

**The social component.** Where the young person is isolated, the schedule includes the specific steps by which contact will be made, and these are graded like everything else.

## 4. Behavioural Activation with Children and Adolescents

### 4.1 The developmental case

The case for behavioural activation with adolescents is stronger than the case for adults, and the reasons are developmental.

**The withdrawal is developmentally costly.** The adolescent's task is the construction of a stable identity through competence and connection, and every week of withdrawal is a week in which the developmental work does not happen. A young person who withdraws at fourteen has a harder task at twenty.

**The adolescent's mood is more behaviourally determined.** The adolescent's emotional state is substantially a function of activity, sleep, and social contact, and the behavioural levers are correspondingly more powerful.

**The cognitive intervention is harder.** A young person with depression is often not able to examine his own thoughts productively, and may find the cognitive model alienating, and behavioural activation gives him a way of working that does not require him to challenge his own perceptions. Many adolescents who refuse cognitive therapy will accept behavioural activation.

**The competence dimension is directly available.** The graded task is a developmental intervention as well as a clinical one, because it generates evidence of competence, and evidence of competence is what the adolescent's self-evaluation requires.

**Social reconnection is a protective factor.** The literature on adolescent development identifies supportive social connection as one of the most robust predictors of good outcomes, and behavioural activation is one of the few treatments that targets it directly.

## 4.2 The specific modifications

**Shorten the monitoring.** A daily log with two ratings, completed in under three minutes, is realistic. The full hourly record is not.

**Complete the first day with the young person.** A depressed adolescent will not start the log unaided, and the session in which the clinician logs the young person's day alongside them is often the session that establishes the alliance.

**Use a social, concrete activity list.** The clinician proposes activities from a list the young person has helped to make, and the activities are named specifically — "walk to the bridge and back" rather than "exercise" — and the specificity is what makes them doable.

**Grade more finely than feels necessary.** The clinician will feel that the steps are too small. They are not.

**Prioritise contact over productivity.** For a withdrawn adolescent, a coffee with a friend is a more valuable activity than a fortnight of revision, and the schedule should say so.

**Build around existing anchors.** The days on which the young person does something already — a music lesson, a shift, a football match — are the days on which the rest of the schedule should be built, and the clinician should look for them in the monitoring.

**Involve the family carefully.** Family involvement supports the schedule and provides the practical conditions, and it also introduces the risk that the schedule becomes a family performance. The young person should be consulted about what is shared.

## 4.3 The management of comorbidity

**Anxiety.** A young person with depression and anxiety presents a specific difficulty: the activities that relieve the depression are the activities the anxiety prevents, and the activities the anxiety tolerates are the ones that do not relieve the depression. The resolution is graded exposure combined with activation, and the principles of Chapter 25 apply, with the added specification that the exposure and the activity are the same activity.

**Trauma.** A young person whose withdrawal is trauma-related is not helped by an activity schedule that pushes them into situations in which they feel unsafe, and the trauma assessment in Chapter 38 comes first. The activity schedule in that case is built inside the young person's window of tolerance, and Chapter 40 develops this.

**Substance use.** A young person who uses substances to manage the depression presents a situation in which the behavioural analysis must account for the function of the substance use, which is frequently relief from the very states the activity schedule is designed to address. Chapter 47 addresses this in detail.

**Apathy and the loss of interest as a symptom.** A young person with depression may not be able to identify any activity they find rewarding, and the monitor may record no pleasure at all. The clinical response is to start with activities that are *mastery* activities and that are physically activating, and to rely on the improvement in energy that follows.

### 4.4 The school context

Depressed adolescents are often not in school, and the school is therefore the setting in which the activation must be designed.

**Attendance as the first target.** A graded return to school, using the first-day design from Chapter 25, is often the first step in the graded task hierarchy, and it is frequently the graded task that has the greatest downstream effect, because attendance unlocks the rest of the school-based activity.

**The school-based activity schedule.** A short daily schedule of specific activities, with at least one social component, agreed with the school, is more effective than a schedule kept at home, because the young person is in the building anyway.

**Coordination with the pastoral team.** The pastoral team is usually already managing the young person's absences and is likely to be applying a monitoring system of its own. The behavioural activation schedule and the school's attendance system should be the same system, and a practitioner who adds a third system has increased the burden rather than reduced it.

## 5. Case Illustration: The Young Person Who Stopped Leaving Her Room

**Presentation.** Nadia is sixteen and has been out of school for seven weeks. She spends her days in her room, emerging to eat and to use the bathroom. Her mother reports that she used to be "loud and funny" and is now "like a ghost". She has not been in the same room as her younger sister for most of the period. Her mother is at work during the day, and the youngest sibling is at school, so the house is empty.

Nadia's own account, given with some reluctance at the fourth session, is that she stopped going in because "everyone's got their group and I'm not in one, and I'm not going to be the new girl again." She has not been to school in seven weeks and describes each morning as "wanting to disappear".

**The assessment.**

*The mood.* Nadia describes low mood, anhedonia, poor sleep, poor appetite, and a loss of energy. The picture is a depressive episode with a marked social withdrawal, and there is no history of mania, of psychosis, and of any previous episode.

*The functional analysis of the withdrawal.* This is where the behavioural work begins, and the analysis is short.

The antecedents of staying in bed are: waking, and the morning's requirement to get dressed and travel. The consequences are: the escape from the demand, and the relief. But there is a second and more important consequence, and the monitoring makes it visible. Nadia's mother, in desperation, brings her breakfast to the room, and stays and talks to her for twenty minutes, and does not make her come down. The mother's attention — which is warm, and is not given under any other circumstances — is contingent on the withdrawal. The mother is reinforcing the withdrawal with the very behaviour that is most sustaining of it, and she is doing it out of love.

The consequences of going to school, by contrast, are that Nadia spends a day in a building where she is not known, is looked at, and is required to interact. The school has been, in effect, delivering a strong punishment for attending.

*The antecedents of the social withdrawal.* Nadia's account identifies a specific trigger: a change of school in the previous year, and a period of a few weeks in which she was not spoken to by anyone. The withdrawal is not a mood that began the absence; it is a response to a specific social loss that was then maintained.

**The formulation.** A depressive episode, maintained by a behavioural cycle: the withdrawal reduces the reinforcing activity, the reduced activity produces a deeper depressive mood, the deeper mood produces a wider withdrawal, and the mother's daily attention to the room sustains the withdrawal behaviour itself. The social anxiety is real and is not a symptom of the depression; it preceded it, and it is the reason the depression is maintained.

**The intervention.** The plan has five elements, and the sequencing is critical.

*Element one: the mother's contingency.* The mother is asked to stop bringing breakfast to the room and to stop sitting with Nadia in the morning, and this is the hardest part of the plan. The reason is explained carefully: the daily attention is what is keeping the pattern in place, and the love that is in the attention is not in question. What is proposed instead is a daily contact that is not contingent on the withdrawal — a fixed fifteen minutes at a fixed time, with a specific activity, in which the mother talks about her own day, and which Nadia may or may not attend. The purpose is to preserve the relationship while removing the contingency.

The mother also agrees to a gradual reduction in the practical support: the breakfast comes to the kitchen, the door is left open, the answer to the question "is Nadia up?" becomes "she's in her room", and the mother's own daily functioning is protected, because a mother who has not slept properly for seven weeks cannot implement any plan.

*Element two: the graded task.* Nadia constructs the hierarchy, with the help of the counsellor, and it runs: get up; get dressed; come downstairs; have breakfast at the table; sit in the garden; walk to the corner; walk to the park; go to the shops; get the bus; go to college.

The first step — get up — is placed at the level where Nadia is confident, and the advance criterion is three consecutive days. The first four steps are all achieved within the first fortnight, and the counsellor does not

push past the fifth step even when Nadia is ready, because the advance criterion is a clinical tool and not a suggestion.

*Element three: the social contact.* The graded task alone produces an improvement in mood that is real but limited, because the tasks are solitary. The schedule therefore adds, in week two, one scheduled contact per day with a named person, and the contact is chosen with Nadia — a former friend, a cousin, a member of the football team Nadia used to play in — and each contact is preceded by a text and is short, and the shortness is the point, because the first successful contact after seven weeks of isolation is a short one.

*Element four: the school.* The graded return to school uses the first-day design. Nadia attends for one lesson in week three, in a subject she does not feel exposed in, with the pastoral support worker, and leaves having spoken to one person. The school plan specifies what will happen in the corridor, which is the place she most fears, and the plan has the pastoral support worker walk with her from the gate to the classroom for the first two weeks.

*Element five: the monitoring continues.* The daily log continues throughout, because it is the data that will show whether the plan is working, and because it is one of the few things in Nadia's life that is structured and predictable.

**The outcome.** At three months, Nadia is in school four days a week, taking three subjects, and is meeting one friend weekly. Her mother reports that the mornings are "normal-ish". The depression has not fully lifted and the work continues, and the partial response is the expected one: behavioural activation works faster on the behavioural symptoms than on the mood, and a young person who has withdrawn for seven weeks does not rebuild a social world in three months.

**The interpretation.** Two features of this case are generalisable. The first is the maternal contingency, which is present in a large proportion of cases of adolescent withdrawal, and which is rarely identified because it presents as care. The second is the ordering of the work: the graded task before the social contact, and the social contact before the school return, because the school return requires a social confidence that the graded task alone cannot supply. A practitioner who sent Nadia to school in week one would have produced a worse outcome than one who did nothing, because the failure would have confirmed her expectation.

# 7. Evidence and Research Support

## 7.1 The status of the evidence

Behavioural activation has a larger evidence base than most psychotherapies, and the findings are unusually consistent. The principal results are as follows.

**Behavioural activation is effective for depression in adults.** The Cochrane and meta-analytic reviews report effect sizes in the large range, and the treatment is recommended in the major international guidelines.

**Behavioural activation is effective for depression in adolescents.** The adolescent literature is smaller but is consistent with the adult findings, and the reviews report moderate-to-large effects on both symptoms and functioning.

**Behavioural activation produces more rapid improvement in mood than cognitive therapy in the acute phase**, and this is the finding that established the treatment's viability as a standalone treatment and that motivated the combination with cognitive therapy.

**Behavioural activation is at least as effective as cognitive therapy on measures of depression severity**, and the two are not clearly different on the outcome measures, though the treatment acceptability data favour behavioural activation, particularly with young people and with people whose symptoms include a predominance of fatigue and anhedonia.

**The combination of behavioural activation and cognitive therapy is probably the most effective treatment for depression in adolescents**, and this is what most guidelines now recommend, with the behavioural component delivered first.

**Behavioural activation has good support in populations that are difficult to engage**, including young people who are reluctant to talk, and the treatment can be delivered by trained non-professionals with supervision, which is relevant to school-based and primary care services.

## 7.2 The component evidence

The treatment is composed of identifiable components, and the component studies are more useful for practice than the outcome studies.

**Activity monitoring** is the component with the weakest independent evidence, and this is a point of some controversy in the field. The counter-argument is that monitoring is not a treatment in itself but a mechanism that makes the discrepancy visible to the young person, and that its value is in what follows rather than in itself. The practical guidance from the evidence is to keep the monitoring brief and to do it collaboratively.

**Activity scheduling** has good support and is the component with the clearest mechanism.

**Graded task assignment** has good support, particularly with young people and in the treatment of depression with apathy, and the evidence for its use in activity scheduling for individuals with severe depression and low energy is reasonably strong.

**The discrepancy between the predicted and the actual quality of an activity** is a well-established finding, and the value of drawing it explicitly to the young person's attention is the therapeutic core of the treatment.

**The primacy of the behavioural component in the acute phase** is supported, and the treatment sequence is to activate first and to cognitively address the remaining difficulties once the behavioural cycle has been interrupted.

### 7.3 Limitations of the evidence

**The adolescent literature is smaller than the adult literature**, and the trials are heterogeneous in the age range, the severity, and the inclusion criteria.

**Long-term maintenance is less well studied than symptom reduction**, and a substantial proportion of young people relapse after the end of treatment, which is consistent with the developmental reality that the conditions that produced the depression may still be present.

**The trials have generally not included the most severely impaired young people**, particularly those with comorbid substance use, with trauma histories, or with neurodevelopmental conditions, and these are the young people most likely to be seen in a school or specialist service.

**The measures are largely self-report**, and the adolescent literature's reliance on self-report of mood is a limitation, particularly in a population whose reporting is affected by the very symptoms being measured.

**The allegiance effects are substantial** in this literature, as they are in the behavioural literature generally.

## 8. Strengths and Limitations of Behavioural Activation

### 8.1 Strengths

**It works quickly.** The behavioural component often produces a measurable improvement in mood within two weeks, and a rapid improvement is itself a therapeutic event, because it gives the young person evidence that the situation can change.

**It is concrete and accessible.** A young person who has been told that their thoughts are distorted usually responds poorly; a young person who is told that they will walk to the park and then come back and tell someone what they noticed is likely to go along with it.

**It is compatible with the developmental task.** The treatment works on the same processes that the adolescent's development requires, and this is a rare alignment.

**It is deliverable by non-specialists.** The treatment can be delivered by a school counsellor, a primary care nurse, or a trained support worker with supervision, and the evidence for the supervised delivery is good.

**It produces data.** The monitoring generates a record that the young person, the family, and the school can all see, and the record is itself a resource in the work with the school.

### 8.2 Limitations

**It is incomplete.** Behavioural activation addresses the behavioural withdrawal and its consequences. It does not address the reason the young person withdrew in the first place, except insofar as the withdrawal is maintained by a contingency, and the social anxiety in Nadia's case required work that the graded task alone would not have provided.

**It can be experienced as a productivity demand.** A young person who is told to "get up, get dressed, go to the park" may experience the schedule as another set of expectations, and the young person who is in the grip of a depressive episode may not be able to comply and will conclude that they have failed again. The clinical response is to make the first steps trivially small and to make the review of the log collaborative rather than evaluative.

**It does not reach the cognitions quickly enough in some cases.** A young person with a strong global negative self-belief may need the cognitive work sooner than the standard sequence allows, and the combination of behavioural activation and cognitive therapy addresses this.

**The maintenance is the problem.** A young person who leaves treatment with an improved mood and an unchanged set of conditions will relapse, and the relapse prevention work of the cognitive tradition should be built into the plan from the beginning.

**It can be misapplied as a compliance programme.** A graded task schedule in a school that is presented to the young person as a set of targets to be met, with consequences attached, is not behavioural activation; it is a compliance programme, and the evidence does not support it.

## 9. Cultural and Ethical Considerations

### 9.1 Culture, activity, and what counts as rewarding

The entire treatment depends on the assumption that the young person will find certain activities rewarding, and that assumption is culturally patterned in ways that require attention.

**What is rewarding is culturally specified.** Activities that are rewarding in one context are not in another: sport, music, religious or spiritual practice, family ceremony, food and cooking, language use, craft, and community activity all vary in their valuing. A clinician who proposes a graded task of "go to the library and read" to a young person for whom reading is associated with academic failure has proposed a task that is unlikely to be rewarding, and the failure will be read as motivation.

**Family obligation may be the available reward.** In some contexts the most reliably reinforcing activity available to a young person is the participation in family obligations and in the family's projects, and this may be the only socially legitimate way to build a schedule. A schedule built around helping at the family's shop, or caring for a grandparent, or the family's shared meals, may be both more effective and more

acceptable than one built around the activities a clinician would nominate.

**Gender expectations shape the available activities**, and a schedule that puts a young woman into activities that expose her to unwanted attention in the community may be actively harmful, and the clinician should ask.

**The stigma of mental illness affects the schedule.** In some settings, a schedule that is visible to the family or the school and that names the young person's difficulties is harmful, and the schedule should be designed to be usable without being explanatory.

## 9.2 The relationship to the body and to appearance

Behavioural activation with adolescents inevitably touches the body, because the activities that relieve depression include physical activity, and because the young person with depression has often stopped eating, exercising, and attending to their appearance. Three cautions follow.

**The activation of physical activity can be experienced as a demand on the body**, particularly for a young person who has experienced body scrutiny, weight commentary, or disordered eating. The activities should be chosen with that in mind.

**Weight gain and appetite disturbance are features of the disorder**, and a young person who is told to eat more, or to exercise, may experience the instruction as an accusation. The clinician should name the symptom as a symptom.

**Anorexia nervosa is not treated by behavioural activation.** The graded task schedule is contraindicated in a young person with a diagnosed eating disorder, and the medical and specialist pathway in Chapter 46 takes precedence. This is an important exception and the practitioner should know it.

## 9.3 Ethical considerations

**Voluntariness.** The activities in a behavioural activation schedule are proposed, not imposed, and the young person chooses from a list. A schedule of activities chosen by the clinician is a different intervention with weaker support and a different ethical character.

**The monitoring and the surveillance boundary.** The daily log is a monitoring device, and the young person should know exactly what it is for, who will see it, and what will be done with it. A log that is shared with the school or the parents without the young person's knowledge is a breach of trust that will damage the alliance and is likely to end the treatment.

**Avoiding the allocation of tasks that should not be allocated.** A graded task hierarchy must not include tasks that the young person is not developmentally able to perform, must not include tasks that function as unpaid labour, and must not include the performance of household duties that other family members should carry.

**The graded task as a performance of recovery.** When the young person's graded task is shared with the family, it can become a public display of progress, which is a burden and can become a source of shame if the progress is slow. The clinician should keep the hierarchy private unless the young person wants it shared.

**The competence dimension and the risk of discouragement.** The graded task generates evidence of competence, and it also generates repeated evidence of failure if the steps are mis-set. The first step must be achievable, and the review must be framed so that a step that is not completed is information about the step

rather than about the young person.

**Coordination with the school must be consented to.** A practitioner who shares a young person's monitoring data with the school without the young person's knowledge has used the data for a purpose other than the one for which they were collected.

## 10. Key Terms

**Key Terms at a Glance**

- **Behavioural activation** — A treatment for depression in which the reduction of reinforcing activity and the increase of aversive activity are treated as the maintaining cycle, and the intervention consists of scheduling and performing rewarding and mastery activities.
- **Activity record** — Jacobson's daily log of activities with ratings of pleasure and of mastery, used to establish the baseline and to make the discrepancy between predicted and actual experience visible.
- **Activity monitoring** — The modern, abbreviated form of the activity record, used as a baseline, as a measure of the relationship between activity and mood, and as the source of the schedule.
- **Activity scheduling** — The specification of what the young person will do, when, and with whom, on a written schedule in three columns.
- **Graded task assignment (GTA)** — A hierarchical list of tasks of increasing difficulty, worked through one or two steps beyond the young person's current position, with each completed step recorded and acknowledged.
- **Task hierarchy** — The ordered list of graded tasks in a graded task assignment, running from currently impossible to currently easy.
- **Advance criterion** — The specified condition for moving to the next step of a graded task hierarchy, usually a number of consecutive completions.
- **Mastery activity** — An activity selected for the sense of competence it produces rather than for its immediate pleasure.
- **Pleasure activity** — An activity selected for the immediate reward it produces.
- **The discrepancy** — The difference between the expected quality of an activity and its observed quality; the therapeutic target of the treatment.
- **Behavioural model of depression** — The account in which depression is maintained by the reduction of reinforcing activity, the increase of aversive activity, the avoidance of non-reward situations, and the disruption of physiological rhythms.
- **Immediacy of reward** — The property of an activity's consequence that determines its reinforcing strength, and the basis for restructuring delayed-reward activities.
- **Certainty of reward** — The predictability of an activity's outcome, which determines its reinforcing strength and the rationale for graded mastery tasks.
- **Social contact in the schedule** — The deliberate inclusion of scheduled contact with other people, which is the component most specific to adolescent depression.

**Key Terms at a Glance (continued)**

- **First-day design for school return** — The practice of beginning a return to school with a single brief, structured, and rewarding visit, before any substantial assessment or homework.
- **Anhedonia** — The loss of the capacity to experience pleasure from activities that would ordinarily be rewarding.
- **Behavioural activation with cognitive therapy** — The combination in which the behavioural component is delivered first, to interrupt the cycle, and the cognitive component follows.
- **Control therapy** — The early behavioural approach to depression based on the restoration of control through graded mastery tasks.
- **Learned helplessness** — The account of the acquisition of a passivity response through exposure to uncontrollable aversive events, with limited application to adolescent depression.
- **Pacing** — The deliberate matching of the task difficulty to the young person's current capacity, with the expectation of variable performance.
- **Behavioural activation for apathy** — The application of activity scheduling and graded tasks to the predominance of fatigue and loss of interest in the depressive presentation.
- **Window of tolerance** — The range of arousal in which a person can function and process information, and outside which behaviour is dysregulated; the constraint within which an activity schedule must be built.
- **Contingency management of the depressive cycle** — The application of the operant analysis to the relationship between the young person's activity, their mood, and the contingencies that sustain the withdrawal.
- **Activation of the social self** — The reintroduction of contact with other people, graded, as the mechanism by which the depressive cycle is interrupted in the adolescent presentation.

## 11. Chapter Summary

Behavioural activation is the treatment that the behavioural tradition contributed to the understanding and treatment of depression, and it rests on a single observation that is older than the cognitive model and, in some ways, more useful: the defining features of depression are not beliefs but withdrawal, and the withdrawal is self-maintaining.

The behavioural model describes depression as a cycle with four processes: the reduction of reinforcing activity, the increase of aversive and numbing activity, the avoidance of situations associated with non-reward, and the disruption of the physiological rhythms. The intervention interrupts the cycle by identifying activities that the person finds rewarding, scheduling them, and performing them, and by adding graded mastery tasks where the young person has stopped doing the difficult things.

The three components were described in detail. Activity monitoring establishes the baseline, makes the discrepancy visible, identifies the pattern, and supplies the data for the schedule, and the chapter noted the three practical responses to the predictable non-compliance with it. Activity scheduling requires the specification of what, when, and with whom, and it must include social contact, because the social

component is the one that distinguishes the adolescent depression from the adult depression and the one that has been lost. Graded task assignment is the component most associated with the treatment, and its rules — achievable but not trivial, chosen by the young person, reviewed weekly, subdivided until the first step is clearly achievable — were set out in full.

The case of Nadia showed the treatment in operation and showed the three elements of the formulation that generalise: the maternal contingency, in which the daily attention of a loving parent was sustaining the withdrawal; the ordering of the work, with the graded task preceding the social contact and the social contact preceding the school return, because a premature return to school would have confirmed the young person's expectation; and the distinction between the depression, which was the presenting problem, and the social anxiety, which preceded it and maintained it.

The evidence is large and consistent for adults and substantial and growing for adolescents, and the findings that behavioural activation produces more rapid mood improvement than cognitive therapy in the acute phase, and that the combination is probably the best available treatment for adolescent depression, are the ones that changed practice. The component evidence favours activity scheduling and graded task assignment, and the chapter noted the controversy over the monitoring component honestly.

The limitations are that the treatment is incomplete, that it can be experienced as a productivity demand, and that maintenance is the central problem, since a young person who leaves treatment with an improved mood and unchanged conditions will relapse. It can also be misapplied as a compliance programme, which is not the same intervention and is not supported by the evidence.

The cultural analysis addressed the specification of what is rewarding, the role of family obligation as the most reliably available reward in some settings, gender expectations, and the stigma of mental illness in the design of a schedule. The ethical analysis addressed the voluntariness of the activity selection, the surveillance boundary around the monitoring, the body and appearance issues that are unavoidable with adolescents, the specific contraindication of graded task scheduling in a young person with a diagnosed eating disorder, and the ethical requirements of keeping the hierarchy private unless the young person wishes otherwise.

## 12. Review and Discussion Questions

**Review and Discussion Questions**

1. Describe the historical development of behavioural activation from Jacobson's activity record to the modern treatment.
2. Explain the contribution of the activity record to the treatment and state its two principal purposes.
3. State the four processes of the behavioural model of depression.
4. Explain how cognition enters the behavioural model, and at what three points.
5. Explain the significance of the immediacy and certainty of a reward for the design of an activity schedule.
6. State the three components of behavioural activation and the function of each.
7. State the four purposes of activity monitoring.
8. Explain the three responses to the predictable non-compliance with monitoring.
9. State the four principles that govern activity scheduling, and explain the social contact principle.
10. Describe graded task assignment, and state its six rules.
11. Describe the session structure of behavioural activation.
12. State the five developmental reasons why the case for behavioural activation is stronger with adolescents than with adults.
13. State the six specific modifications required for young people.
14. Explain the difficulty of the comorbid anxiety presentation and the resolution.
15. Explain the role of attendance as a graded task in the school context.
16. Describe the case of Nadia, and state the three features of the formulation that generalise.
17. State the four elements of Nadia's intervention and explain the ordering.
18. Summarise the status of the evidence for behavioural activation with adults and with adolescents.
19. Summarise the component evidence, and state the controversy over the monitoring component.
20. State the five limitations of the evidence base.
21. Explain the four strengths and the five limitations of the treatment.
22. Explain how the assumption that certain activities are rewarding is culturally patterned.
23. Explain the significance of family obligation as an available reward in some settings.
24. State the three cautions relating to the body and to appearance, and the specific contraindication of the treatment in a diagnosed eating disorder.
25. State the five ethical requirements for behavioural activation with young people.

## 13. Practice Activities

**Practice and Application**

### Activity 27.1 — Your Own Activity Record (three days, individual)

Complete a two-column activity record for three days, with a pleasure rating and a mastery rating against each activity. Do not complete it retrospectively. On the fourth day, plot the mood rating against the activity and identify the relationship. Then write two sentences describing a discrepancy you found — something you expected to be unpleasant that was not, or something you expected to be pleasant that was not. The exercise is the treatment in miniature, and every student finds at least one discrepancy they had not noticed.

### Activity 27.2 — Building a Graded Task Hierarchy (75 minutes, individual)

Choose a young person from placement who is withdrawn. Construct a graded task hierarchy of at least twelve steps, running from currently impossible to currently easy, with the steps specified in the units in which the young person would actually do them. Then check the first step against the criterion: is it something the young person is confident they could do today? If not, subdivide and repeat. Most hierarchies fail this test at the third or fourth step, and the exercise is designed to make that visible.

### Activity 27.3 — The Social Contact Ladder (60 minutes, small group)

In groups of three, design the social reintroduction component of a behavioural activation plan for a withdrawn sixteen-year-old. Specify a graded ladder of contacts, the people involved, the duration of each, the preparation for each, and what is done if the young person refuses. Then discuss what the group would do if the young person said she did not want to see any of the people the group had chosen. The last part is the most instructive, because the answer is almost always that the young person chooses a different person, and the reason she could not choose one initially is the point.

### Activity 27.4 — Auditing a Schedule for Coercion (45 minutes, individual)

Take any activity schedule you have seen or designed, and audit it against five criteria: was the activity chosen by the young person; is the monitoring private; is the graded task free of tasks that should be allocated to others; is the schedule free of tasks that are unsafe for the young person; and is the first step achievable today? Count the failures. The exercise is a short version of the ethical analysis, and the failures are usually found in the monitoring rather than in the schedule.

## 14. Annotated Reading Pathways

**For the treatment.** Read Jacobson (1971) for the original account and Jacobson and colleagues (2001) for the controlled comparison with cognitive therapy, and read Rehm (2011) for the modern synthesis. The Jacobson material is old and the concepts are current, which is a rare and useful combination.

**For the evidence.** Read the adolescent review literature on behavioural activation and read the meta-analyses of the adult literature, and then read a study with a component analysis, which is more useful for practice than the outcome trials.

**For the developmental adaptation.** Read the adolescent development literature on the role of competence and connection, and read the treatment adaptation papers for young people. The developmental rationale is what makes the modifications in Section 4 principled rather than ad hoc.

**For the combination with cognitive therapy.** Read the cognitive model chapter in this book alongside the activation material, and read the studies of the combination, which is the treatment most likely to be used in practice.

**For the cautions.** Read the eating disorder and adolescent depression literature, particularly on the contraindication of behavioural activation in anorexia nervosa, and read the literature on activity monitoring as a burden.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Behavioral Activation and Activity Scheduling** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is the behavioural treatment of depression and withdrawal in adolescents. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is functional analysis, learning history, contingencies, mastery, and measurable behaviour change. The mechanism to keep in view is how antecedents, consequences, skills, avoidance, and environmental design select and maintain behaviour. The characteristic professional risk is using control without assent, reinforcing compliance rather than wellbeing, or ignoring the meaning and function of behaviour. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 7. Apply the method | Use the chapter's core procedures in classrooms, homes, clinics, and other real environments where behaviour occurs, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support,

timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Priya is fifteen and is seen in a school counselling service for low mood and withdrawal from friends. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Priya's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Priya explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on functional analysis, learning history, contingencies, mastery, and measurable behaviour change. The first intervention is deliberately modest. Priya chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Priya has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Priya can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be

sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Behavioral Activation and Activity Scheduling

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Behavioral Activation and Activity Scheduling** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

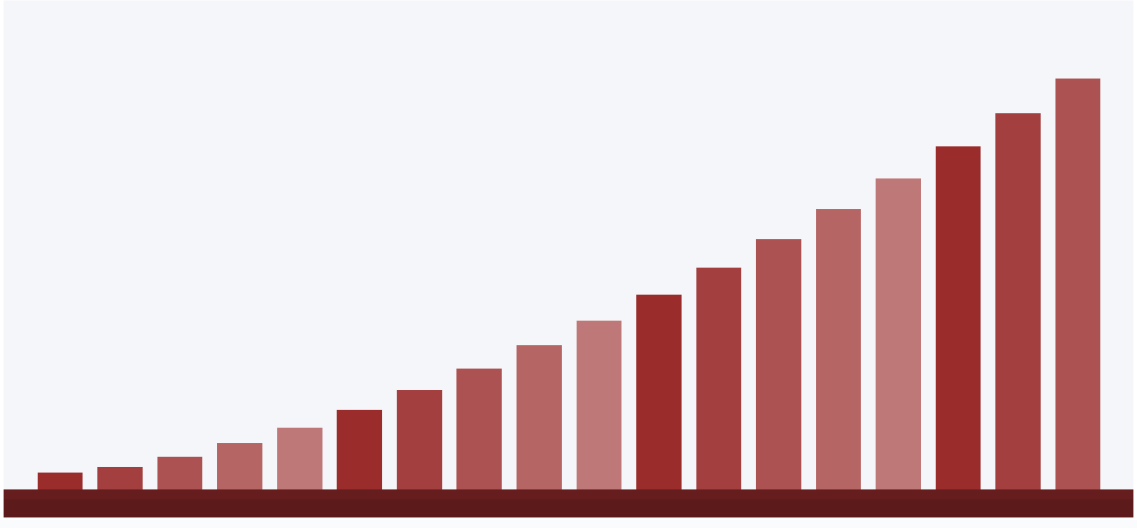
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Behavioral Activation and Activity Scheduling** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Behavioral Activation and Activity Scheduling**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into



clinical governance.

**Written consolidation.** In 250 words, explain Behavioral Activation and Activity Scheduling to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 28

# Contingency Management in Schools and Clinics

Token systems, behaviour contracts, and the negotiated restructuring of reinforcement in real settings.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the rationale for using contingency management in schools and clinics, and state the conditions under which it is appropriate.
- Describe the design and implementation of a token economy in a classroom setting.
- Explain the design of a behaviour support plan, and describe the elements it requires.
- Describe the construction of a behaviour contract, and state its limits in the school context.
- Explain the role of the classroom teacher, the teaching assistant, and the parent in a contingency management programme, and describe the training they require.
- Describe the management of a classroom in which the behaviour of a small group is disrupting the class.
- Apply contingency management to a case in a school or clinic, and evaluate the ethical constraints.
- Critically evaluate the cultural and ethical dimensions of contingency management in institutional settings, and state the legal and regulatory context.

## Chapter Overview

Contingency management is the most direct application of the operant principles of Chapter 26 to a real setting, and it is also the application with the largest gap between its technical simplicity and its practical difficulty. The technique is easy to describe: define the target behaviours, define the consequences, make the consequences contingent, and review. The difficulty lies in the fact that a school is an organisation of many people, each of whom responds to a young person's behaviour, and a contingency system is only as good as the weakest of those responses.

The failure mode is predictable and it is the central clinical problem of this chapter. A programme is designed with the class teacher. The teaching assistant is not told. The dinner supervisor is not told. The supply teacher, who covers on the two days a week the class teacher is absent, is not told. On the first day the supply teacher sees a pupil being disruptive and responds with the customary escalation, and the pupil learns that the classroom contingency holds on Tuesday and Thursday and not on Wednesday. Two weeks later the data look like a mystery, and the practitioner must decide whether the hypothesis was wrong or the implementation was inconsistent, and the honest answer is usually the second and the diagnosis is usually harder than it should have been.

The other central theme is the status of the system within the setting. A token economy introduces an explicit exchange relation between the adult and the young person, and in a school that exchange is visible to peers. This is not a minor consideration: for a young person who is already struggling with status, a visible system of rewards and penalties can be more damaging than the behaviour it addresses. The practitioner must decide, in each case, whether the system is visible, and the decision is not always "no".

This chapter presents the technical design of school and clinic contingency systems, the implementation requirements that make them work, the failure modes, and the ethical and legal framework that applies.

## 1. The Setting as a Contingency System

## 1.1 Every setting is already a contingency system

The single most useful clinical idea in this chapter is that a school, a clinic, and a family are already systems of contingencies, operating whether or not anyone has designed them. The question is never whether to introduce consequences into a setting; the setting is already full of them. The question is only whether the consequences are the ones that serve the young person.

The inventory is short and it is diagnostic. For any behaviour that concerns a practitioner, the inventory asks: what happens immediately after it, for the young person, for the peers, and for the adult; what happens immediately before it; who is present; and what is the young person's alternative.

Three findings are common.

**The problem behaviour is reinforced.** The pupil who is sent out of class gets to leave a boring lesson; the pupil who is shouted at gets attention; the young person who refuses to attend gets to remain with the family. These are the classic patterns and they are everywhere.

**The desired behaviour is unreinforced.** The pupil who works quietly for forty minutes receives nothing; the pupil who asks for help is sent away; the young person who attends on time and quietly is invisible.

**The adults are inconsistent.** Two teachers in the same corridor respond to the same behaviour differently, and the young person has learned that the inconsistency is exploitable.

## 1.2 Why schools and clinics are the right sites for this work

Three features make schools and clinics the natural settings for contingency management.

**The contingencies are there.** The school's own organisation produces the reinforcements and the punishments; the practitioner does not have to build a system from nothing, only to change the existing one.

**The consequences are legitimate.** A school can legitimately offer a young person access to a preferred activity, a place on a team, a reduced homework load for a defined period, a role in a responsibility group. These are things the school controls and things the young person values.

**The setting is where the behaviour happens.** A behaviour changed in the clinic and not in the corridor has not been changed, and the school is the only place where the corridor behaviour can be observed and modified.

## 1.3 When contingency management is appropriate

Contingency management is appropriate when the following conditions are met, and the practitioner should be able to state the reasoning for the decision in each case.

**The behaviour is clearly defined and is a problem in itself.** The target must be observable and countable, and the case for changing it must be made in terms of the young person's or the setting's functioning, not in terms of the adults' convenience.

**The behaviour has been assessed.** A contingency designed on the basis of a guess is a guess with consequences attached, and a consequence that is wrongly specified is worse than no consequence, because it teaches the young person that the system's rules are arbitrary.

**The consequences are within the organisation's power to deliver.** A school cannot deliver a consequence that depends on another agency, and a clinic cannot deliver a consequence that depends on the family, unless the family is in the plan.

**The young person can succeed.** A contingency that the young person cannot meet has failed, and the response to failure is to adjust the system, not to increase the stakes.

**There is a plan for the transition.** A contingency system that is introduced and never withdrawn becomes a permanent dependency, and a young person's dependence on a system of external rewards is a developmental regression.

**The young person, or the group, has been consulted.** A system imposed on a group of students will be resisted, and the resistance will be rational.

### 1.4 When it is not appropriate

Contingency management should not be used where the behaviour cannot ethically be shaped, where the young person lacks the capacity to understand the system, where the consequence would be a deprivation of a right, or where the system's real function is to control rather than to teach.

A special caution is required in the case of young people with severe cognitive impairment. A token economy is dependent on the young person's understanding of the exchange, and a young person who does not understand it will respond to it randomly. For these young people, the contingencies must be direct and immediate and the system must be supported by the adults, and the plan for fading must be correspondingly slower.

## 2. The Token Economy

### 2.1 The design

A **token economy** in a classroom is a system in which specified behaviours are reinforced with tokens, which are exchangeable at a specified time for specified backup reinforcers. The design requires six decisions, and each of them is a decision that is usually made implicitly and should be made explicitly.

**The target behaviours.** A small number, clearly defined, observable, and countable, and chosen because their change matters. In a class of twenty-five with three pupils who are disruptive, the targets might be: hands up before speaking, remaining seated during the lesson, and completing the first three questions of the starter task. Six targets would be unworkable.

**The reinforcer.** The token itself, or an immediate item. The tokens should be small, durable, collectable, and immediately delivered. The backing reinforcers should be chosen by the young people and should be realistically obtainable.

**The schedule.** The density of reinforcement determines the behaviour. A dense schedule produces a rapid establishment; a sparse schedule produces a generalisation failure. The thinning plan should be written down from the beginning.

**The exchange procedure.** When, where, and by whom the tokens are exchanged. The exchange should be frequent, should be a positive event, and should not be a source of administrative friction for the staff.

**The response cost.** Whether tokens are lost for specified behaviours, and what the loss procedure is. The response cost should be small, immediate, and never a deprivation of a right.

**The fade plan.** The schedule on which the system will be withdrawn, and the criteria for withdrawal. A token economy with no fade plan is a permanent system.

## 2.2 The implementation

The implementation requirements are the part that determines success, and they are the part most often under-specified.

**Staff training.** Everyone who will deliver a token must be trained. The training should include, at a minimum: what the target behaviours are; what to do when they occur and what not to do; what to say and what not to say; how to deliver the token promptly and neutrally; and what to do in the situations that the training predicts will be difficult.

**A rehearsal.** The training should include a rehearsal, in which the staff practise delivering tokens in the presence of a simulated disruption, and in which the appropriate responses to the difficult cases are agreed.

**A written protocol.** The protocol should be on the desk, in the classroom, in the language of the setting, with the target behaviours, the responses, and the exception procedures. A protocol in a file in the office is not used.

**A monitoring system.** A record of the tokens delivered, which is both the fidelity check on the implementation and the data on the behaviour.

**A weekly review.** The review examines the data, the implementation fidelity, and the young people's own views, and it makes the adjustments.

## 2.3 Group versus individual systems

A class-wide token economy is a different instrument from an individual one, and the choice should be deliberate.

**The class-wide system** treats the class as a unit, with the consequences delivered to the class. It is simpler to administer, it does not single out any young person, and it has a significant additional effect: it changes the peers' behaviour towards each other, because a pupil who does not want to lose the class's tokens will manage a disruptive pupil in ways the teacher cannot.

The class-wide system has three limitations. It cannot address an individual young person's specific behaviour, because the consequences are too coarse. It risks the competitive dynamic in which a strong pupil dominates the token economy. And the target behaviours must be ones the whole class can achieve, which constrains them.

**The individual system** is more precise, more informative, and more visible to peers, and it is the appropriate choice for a young person working on a specific behaviour.

**The hybrid** is usually the best: a class-wide system for the shared classroom behaviours, and an individual system for a named young person working on a specific goal, with the individual system structured so that it is not publicly displayed.

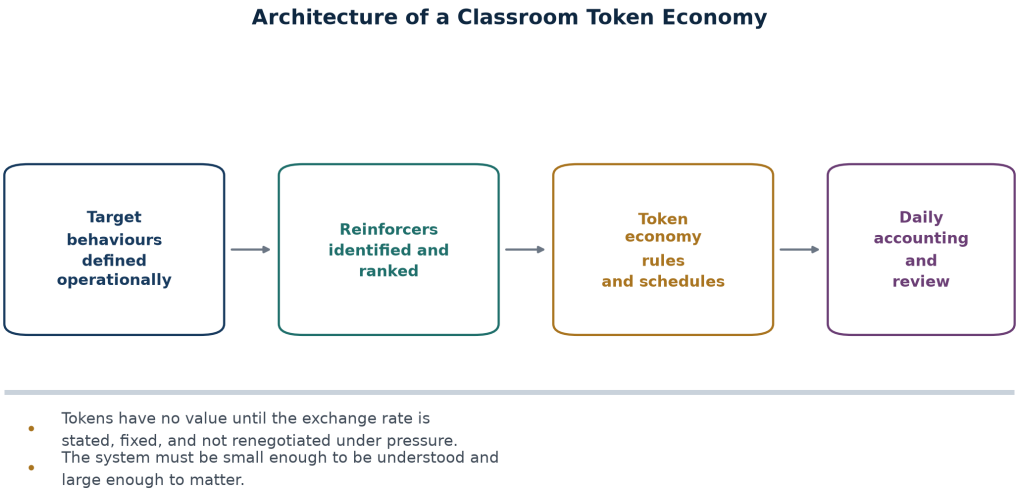


**Figure 28.16** A classroom token economy showing the target behaviours, the tokens awarded, the exchange table, the response cost rules, and the weekly review cycle.

### 2.4 The problems specific to token economies

**The contamination of the target behaviour.** Tokens become a currency, and young people learn to produce the behaviour for the token and to stop when the token stops. The fade plan is the only answer.

**The peer problem.** A visible token system makes some young people targets, and a young person with a history of being bullied may be in greater danger with tokens than without.

**The staff problem.** Token delivery is additional work, and the adults who do it least are usually those with the greatest need, and the result is an inconsistent system.

**The dismissal problem.** A pupil who is sent out of the classroom loses the opportunity to earn tokens, and the removal from the class is also a removal from the reinforcement system, which is why a token economy and an exclusionary response are incompatible in the same plan.

**The reward problem.** The backup reinforcers must be genuinely valued and genuinely available, and a school that promises a reward it cannot deliver, or that offers only what the young person considers worthless, has damaged the system rather than established it.

## 3. Behaviour Support Plans

### 3.1 The function

A **behaviour support plan** is the written document that specifies, for a named young person, the target behaviours, the strategies to be used, the contingencies, the roles of the adults, the data to be collected, and the review arrangements. It is the formalisation of contingency management for an individual, and it is the document that most schools lack and most need.

The function of the plan is partly clinical and partly organisational. Clinically, it ensures that the adults are working from a common specification rather than from individual impressions. Organisationally, it is the document that the practitioner can take to a meeting, and that survives a change of staff, and that can be reviewed.

## 3.2 The elements

**Student and staff information.** The young person's strengths, interests, and preferences; the adults involved and their roles; the timetable of the adults, so that the plan can be matched to the staffing.

**Target behaviours.** Stated in operational form, with the baseline data, and with the target specified in a way that is measurable.

**Strategies.** The specific techniques: differential reinforcement, planned ignoring, a specified response to disruption, a break procedure, a de-escalation script. The strategies should be specific enough to be followed and few enough to be remembered.

**The contingencies.** The rewards and the response costs, with the schedule.

**The response to escalation.** A specified, graduated, and rehearsed procedure, with the point at which the young person is removed from the setting and what is said when that happens. This element is the one most often missing and the one most responsible for failure, because when a young person escalates, the adult's improvised response is the treatment.

**Data collection.** What is recorded, by whom, and how the data are reviewed.

**A review schedule**, and the criteria for ending the plan.

**The involvement of the young person.** The young person's own words, their own goals, and their agreement, should be in the plan.

## 3.3 The graduated response and the escalation procedure

The escalation procedure should be specified in advance, in writing, and be common to all the adults, and it should include a clear statement that the removal from the class is itself a consequence and that the return is the reward. The commonest errors are to remove without a specified return condition, to remove with a variable duration, and to allow the young person to return as soon as they are calm, which reinforces the escalation, because the fastest route back is the loudest.

A better procedure specifies that the return is conditional on the completion of a defined task, and that the duration of the removal is short and fixed, and that the young person is accompanied on the return.

## 3.4 The behaviour support plan and the law

A behaviour support plan in a school is a document with legal and regulatory implications, and the practitioner must know the jurisdiction. In the United States, the framework is the Individuals with Disabilities Education Act, under which a behaviour that results in a change of placement is a manifestation of a disability, under the discipline procedures of IDEA, and under Section 504 of the Rehabilitation Act the protections apply to students with disabilities in any setting. The protections include the requirement of a functional behavioural assessment before a change of placement for a student with a disability, and the requirement that the plan be developed by a team.

A practitioner in a school who writes a behaviour support plan without checking the regulatory context is taking a legal risk as well as a clinical one, and the check takes ten minutes. The equivalent framework in the United Kingdom is the statutory framework of behaviour support and, for example, the Equality Act 2010 and the Children and Families Act 2014; elsewhere the practitioner must identify the local equivalent.

The principle is the same everywhere: the plan for a young person with a disability or with a special educational need is a document with legal standing and not merely a clinical convenience.

## 4. Behaviour Contracts in the School Context

### 4.1 The form

A school behaviour contract is a written agreement between a young person and the school, or between a young person and a class, in which specific behaviours are specified in return for specific consequences. The most useful form in the secondary school is the **class contract**, in which the class as a group agrees to a small set of behaviours in return for a set of privileges, and in which the young people have participated in drafting it.

The advantages of the class contract over the class-wide token economy are that it requires no currency, no counting, and no exchange procedure, and that it is far more visible and comprehensible to parents and to a school board. Its disadvantages are that it is less precise, that it is harder to modify mid-term, and that it has no natural fading mechanism — a class contract is typically a term-long arrangement, and the natural conclusion of it is its renewal, which is a decision that has to be made deliberately.

### 4.2 The limits

A behaviour contract in a school must not contract for the removal of a young person's rights: not for access to education, not for access to meals, not for access to the toilet, not for the removal of a statutory exclusion, and not for the removal of access to a member of staff who is the young person's advocate. A contract that trades an educational entitlement for compliance is unlawful in most jurisdictions, and a contract that trades it for a privilege is likely to be so.

A contract must also be genuinely voluntary, which in a school means that the young person can decline to sign without an academic or behavioural consequence, and the practitioner should be prepared for the case where the young person declines and the school wants to know what to do. The answer is to use the class contract, which involves the young person as a member of a group rather than as an individual signatory.

## 5. Case Illustration: The Class That Had Stopped Listening

**Presentation.** Mr Adeyemi teaches a Year 8 class of twenty-eight in a large secondary school. The referral from the pastoral team says that the class is "out of control" and that three students are responsible for the disruption. Mr Adeyemi has been teaching for twenty-two years and is close to the end of his tether. The head of year wants the class split.

**The assessment.** The practitioner asks for the data before the plan.

The class's behaviour log shows something that the referral has not. The disruption is concentrated in a single lesson, the last lesson on a Tuesday afternoon, and it is concentrated in a specific thirty-minute activity: the teacher setting a written task with a thirty-minute independent working period. The lesson before it — the same subject, the same class, the same teacher, an hour earlier — has a behaviour log with almost no entries. The difference is the activity, not the class, and the difference is not the teacher.

The practitioner observes the lesson. The pattern is clear. At the start of the independent working period, Mr Adeyemi sets the task and then circulates to the students who are stuck. This leaves the students who are working unattended, and three of them — the ones the referral names — start talking. The noise rises. Mr Adeyemi returns to the front and says, in a voice the class has heard a thousand times, "Some people are finding this really hard." The class knows who he means. The three boys laugh, because the statement is a ritual and not an instruction, and the two students nearest them join in, and the class as a whole spends the last fifteen minutes of the lesson in a low-level state of disruption that no single student could be held responsible for.

**The functional analysis.** This is a classroom-level functional analysis, and it is the analogue of the individual analysis of Chapter 24.

*Antecedent.* An unsupervised independent working period, and the teacher's attention leaving the class.

*Behaviour.* Talking, escalating to noise, occasional refusal to work.

*Consequence.* A ritualised, non-specific warning from the teacher, followed by the teacher's return to the front, followed by the class's attention, which is entertaining. The behaviour reliably produces a change in the adult's activity and a change in the attention of the class, and it does so whether or not it produces any work.

The behaviour is maintained by **peer attention**, and the adults' ritualised response, which is intended as a signal of disapproval, is a form of attention that the class reads as a signal of significance. This is the most common classroom dynamic the practitioner will encounter, and it is invisible in a referral that describes a "disruptive class".

**The plan.** Four elements, and the plan is a plan for the whole class.

*Element one: change the antecedent.* The independent working period is broken into shorter segments with a defined check-in at the end of each, and Mr Adeyemi's circulation is planned, with a defined route that keeps him in view of the class, and with a defined task during the circulation — a "look at this" card that he uses to ask a student a question about their work, which gives him a legitimate reason to be at the back of the room and keeps his attention available to the whole class.

*Element two: the class contract.* The class agrees to a set of behaviours — three of them, drafted with the students — in return for a set of privileges that the class chooses, and the privileges are things the school can deliver: the last five minutes of the lesson for a chosen activity, a weekly slot in the school newsletter's quiz section, and a class vote on the music for the last lesson. The contract is displayed in the room, signed by the students, and reviewed at the half-term.

*Element three: the response to disruption.* The teacher response is specified in advance and is the change with the largest effect. When the noise rises, Mr Adeyemi does not address the class; he addresses the students who are working, and he says something that acknowledges them specifically — and the class is told in the first week that this is what happens. The three boys are not named, and the class is not told to notice who is being addressed. The logic is that the previous response was a public ritual of generalised disapproval, and the new response is a public signal that the working students are the ones the teacher's attention is for.

*Element four: the data.* Mr Adeyemi records the number of interventions and the number of students working at the end of each of the last ten minutes of the lesson, and the class's work output. The recording is minimal, and the review is with the practitioner every fortnight.

**The outcome.** The interventions drop substantially in the second fortnight and the working output rises. Mr Adeyemi's own summary is that the class is "not the same" and that the biggest change was not the class contract but the change in what he did when the noise started. The head of year withdraws the request to split the class.

**The interpretation.** The case illustrates the central theme of this chapter. The referral described three students; the analysis described a class-wide response pattern maintained by an adult's ritual, and the plan that changed the adult's behaviour changed the class. It also illustrates the theme of implementation: the plan required a teacher to change a deeply ingrained classroom habit, and the fortnightly review with the practitioner was the mechanism that sustained the change, because the old habit returns within days of the plan lapsing.

# 7. Implementation: The Part That Determines Everything

## 7.1 The fidelity problem

The single most reliable finding in the school-based applied literature is that the outcome is determined by the fidelity of the implementation, and the school-based studies that measure fidelity and find it low report null results that reflect the implementation rather than the intervention. The practitioners who design programmes are systematically the ones who implement them least, because the work of teaching is what occupies the time.

Four measures make the difference, and they should be built into any plan from the beginning.

**A written protocol**, in the room, in short form, with the target behaviours, the responses, and the exception procedures.

**A staff training session**, including a rehearsal, and a refresher at the start of each term.

**A fidelity check**, in which the practitioner or a colleague records whether the response was delivered as specified. The fidelity check is uncomfortable and it is the most useful thing in the plan, because it converts "this isn't working" into "this is being delivered 40 per cent of the time".

**A short review cycle.** Fortnightly is usually right. A monthly review is too slow to catch a drift; a daily review is not sustainable for a practitioner with a caseload.

## 7.2 The problem of the adult who is not on the plan

Any school-based plan has to specify what happens with the adults who are not on it. The options are: train every adult who will have contact with the young person, which is the best option and is often impossible; or specify a small number of responses that any adult can apply, which is the second best; or accept the inconsistency and design the plan to survive it.

The third option is not a failure. A plan that survives inconsistent implementation is a robust plan, and robust plans are built on the antecedents and the consequences that are most widely available. The "first day" design of Chapter 25 is robust in this sense, because the young person's own action is the treatment.

## 7.3 The problem of turnover

Staff turnover destroys school-based interventions with a regularity that practitioners underestimate. A plan that depends on a named adult's consistent implementation is a plan with a shelf life of one or two terms.

Three responses help. Build the plan around the classroom environment rather than around the teacher's skill, so that it survives the teacher's departure. Train the whole class in the routine, so that the class maintains it. And put the plan in a form that a relief teacher can follow in thirty seconds.

## 7.4 The problem of the young person who is not in the room

Contingency management assumes the young person is present when the contingency operates. In a school, the young person is frequently not present: they are at the office, in the inclusion room, in the corridor, at the dentist, in a fixed-term exclusion. A plan that delivers a reward at the end of the lesson to a young person who was in the corridor for the last twenty minutes will teach the young person that the corridor is the place

to be, because the reward is available at the corridor's end too.

The specification should say explicitly what happens to the rewards accumulated during an absence, and in most systems the correct answer is that they are held and available on return, with a stated rule about the maximum accumulation.

### 7.5 The problem of the young person who declines

A young person who refuses to participate in a contingency programme presents a question that the practitioner should be ready for, and the answer depends on the young person.

Where the young person is refusing because the plan is not what they want, the plan should be renegotiated, because a plan the young person does not accept will not be implemented. Where the young person is refusing because they do not believe the system will be honoured, the first task is to honour it exactly as written for long enough to build the credibility, and the practitioner should say openly that this is what is happening. Where the young person is refusing because the behaviour is being maintained by something the plan does not address — and this is the most common reason — the plan is wrong and the functional assessment must be revisited.

## 8. Evidence and Research Support

### 8.1 The status of the evidence

The evidence for school-based behavioural intervention is substantial and mature, and it is strongest in three areas.

**Classroom-level interventions.** The class-wide function-related intervention team and its relatives have good support for reducing the level of disruption in a classroom, and the effect sizes reported in the meta-analyses are large, particularly on the proximal outcomes of on-task behaviour and teacher-directed talk. The limitations are the modest effect on the individual student's academic outcomes and the dependence on the teacher implementation.

**Token economies.** The evidence for classroom token economies is good for the reduction of disruptive behaviour, and the older institutional literature is extensive. The modern evidence is thinner than the practice.

**Function-based support plans.** Plans built on a functional behavioural assessment, and delivered consistently, produce better outcomes than plans built on the behavioural reduction model, and the finding is consistent with the applied evidence in Chapter 24.

**Contingency management for substance use.** The school-based and clinic-based applications of contingency management in the treatment of substance use have some of the largest measured effects in the psychological literature, and Chapter 47 develops this.

### 8.2 What the evidence says about implementation

Three findings are more useful to a practitioner than the outcome studies.

**Fidelity determines the outcome.** Where fidelity is measured, it is usually low, and the studies with high fidelity show larger effects.

**Training alone is insufficient.** Staff training improves knowledge and does not reliably improve implementation, and the addition of a written protocol, a rehearsal, and a monitoring process is what produces change in behaviour.

**Classroom-level systems have larger effects than individual-level systems** for classroom-wide outcomes, and the reason is that the classroom-level system changes the peer ecology, which the individual system cannot.

### 8.3 Limitations of the evidence

**The outcomes are proximal.** The studies measure the behaviour in the classroom, and the distal outcomes — the attainment, the family relationships, the mental health, the educational trajectory — are rarely measured, and the assumption that the proximal gains produce the distal gains is an assumption rather than a finding.

**The samples are selected.** The studies are frequently conducted with the classes and the students who are easiest to include, and the young people with the most severe needs and the least predictable attendance are systematically under-represented.

**The implementation conditions are exceptional.** The published studies are frequently conducted by the developers of the intervention, in schools with the resources to support the research, with the research team providing the training that a school would have to provide for itself.

**The evidence is Anglo-American and context-specific.** A token economy depends on the availability of certain backup reinforcers, on the currency of the tokens, and on the institutional culture of the school, and the transferability across systems is limited.

## 9. Strengths and Limitations of Contingency Management in Institutions

### 9.1 Strengths

**It is the clearest and most teachable form of the behavioural principles**, and it is the point at which the abstract concepts of reinforcement become visible and manipulable to a team.

**It produces rapid, measurable change**, which is essential in a setting where the young people who are referred have already experienced many slow interventions.

**It is compatible with the rest of the school's disciplinary framework**, because it specifies the consequences rather than replacing them.

**It involves the adults**, and the process of writing the plan with the teacher is itself a useful clinical intervention, because it forces the adult to state explicitly what they are currently doing and why.

**It can be adapted to any setting**, from a classroom to a clinic to a residential unit.

### 9.2 Limitations

**It is only as good as the implementation**, and school-based implementation is a chronically unreliable enterprise.

**It can be experienced as punishment.** A young person who is subject to a visible token economy in a school where the rest of the students are not may experience it as a punishment, and in some settings the removal of privileges in the name of a token system is indistinguishable from the removal of privileges in the name of a sanction.

**It is easily turned into a control system rather than a teaching system.** A system that removes more than it rewards, that is applied to a class rather than to a person, and that is not reviewed, has become a control system, and the literature on institutional practices makes this abundantly clear.

**It says nothing about why the behaviour occurs.** A young person whose disruption is maintained by a peer dynamic, by a learning difficulty, or by a family situation will not be helped by a well-run token economy, and the practitioner should be alert to the displacement of the problem.

**It is rarely faded.** A great many token economies in schools are in their third year, and the young people in them are correspondingly unable to work without them.

# 10. Cultural and Ethical Considerations

## 10.1 The market objection in the school

The ethical objection discussed in Chapter 26 is sharper in a school, because a school is an institution with an authority relation to the young people in it, and because the peers can see.

Four points follow, and they are the practical requirements of any school-based system.

**Never trade a right.** No system may condition access to education, to meals, to the toilet, to safety, to advocacy, or to a statutory process on behaviour. This is a legal requirement as well as an ethical one, and a practitioner who proposes a system that breaches it is proposing an unlawful arrangement.

**Never trade attention or warmth.** The adults' attention and warmth are not the currency. The specific practical prohibition is that the adults do not use praise and approval as the tokens, because that makes the adults' regard conditional on the young person's performance, and because it is the practice that most reliably produces a compliant and dependent young person.

**Never make the system public if it would humiliate.** For a young person who is already a target, the visible token chart is a hazard, and the design should protect them. The individual system should be delivered without a public display, and the class system should be designed so that the tokens are not individually visible.

**Do not let the system replace the relationship.** A class-wide system that reduces the disruption and fills the lesson with token administration can produce a classroom in which the teacher and the class no longer talk to each other, and this is a real and documented outcome, and the practitioner should watch for it.

## 10.2 Cultural considerations

**The reinforcers available in the school reflect the school's resources and values.** A school in a community with a strong culture of sporting achievement can offer access to the team; a school in a community where that is not valued cannot. The token economy must be built from what is genuinely available and genuinely valued in that community.

**The response to disruption is culturally patterned.** In some school cultures, a public correction is the ordinary way of maintaining order, and a practitioner who introduces a subtler response must be prepared to explain it and to support the teacher in it, because the teacher will be managing the reactions of colleagues.

**The status of the individual in the peer group determines the viability of the system.** A system that signals compliance as a virtue is received very differently by a young person whose peer group values defiance, and a practitioner should establish what the peer group rewards before designing a system that asks the young person to move against it.

**The discipline and the support frameworks are culturally and legally specific**, and a practitioner working outside the jurisdiction in which they trained must learn the local framework before writing a plan.

### 10.3 Ethical requirements

**Consultation and assent.** The young person and, where the system applies to a class, the class must be consulted. A system imposed on a group will be resisted, and the resistance is rational.

**Proportionality and the least restrictive option.** The consequences must be proportionate to the behaviour, and the less intrusive alternatives must be considered and recorded.

**Protection from the aggregation of power.** A behaviour support plan that concentrates the authority of several adults over one young person without review is a risk, and the plan should specify the review point at which the accumulation is examined.

**Documentation and the right to see it.** The plan, the data, and the reviews should be documented, and the young person and the family should be able to see them.

**Review with the family and with the young person, on a stated cycle**, with the question "is this plan still necessary?" included in the review.

**The end of the plan.** Every plan should have a stated end, and a plan with no end is a plan that has become the young person's accommodation.

**The recognition of the possibility of harm.** A practitioner who is introducing a system into a school should be able to state what harm the system might do, and how they would know, and what they would do. In most cases the answer involves the young person's peer relationships, and the answer is not usually "nothing".

## 11. Key Terms

**Key Terms at a Glance**

- **Contingency management in a setting** — The deliberate restructuring of the reinforcement structure of a classroom, a clinic, a ward, or a family, with specified behaviours, specified consequences, trained staff, and a review cycle.
- **Token economy** — A system in which specified behaviours are reinforced with tokens exchangeable for specified backup reinforcers.
- **Token** — The small, durable, immediately delivered item used as the conditioned reinforcer in a token economy.
- **Backup reinforcer** — The item or privilege for which the tokens are exchanged.
- **Exchange procedure** — The specified manner, time, and place at which tokens are converted into backup reinforcers.
- **Response cost** — The specified, small, and immediate loss of tokens following a targeted behaviour.
- **Fade plan** — The written schedule on which the token economy will be withdrawn, with the criteria for withdrawal.
- **Class-wide system** — A token economy applied to a whole class, with the consequences delivered to the class as a unit.
- **Individual system** — A token economy applied to a named young person for a specific target behaviour.
- **Contamination of the target behaviour** — The process by which the behaviour becomes contingent on the token rather than on the contingencies of the young person's life.
- **Behaviour support plan** — The written document specifying a young person's target behaviours, strategies, contingencies, adult roles, data collection, and review arrangements.
- **Graduated response procedure** — The specified, rehearsed, and consistent sequence of adult responses to increasing levels of disruption.
- **Escalation procedure** — The specified adult response to a young person's escalation, including the condition for the return to the setting.
- **Return condition** — The specified requirement that must be met before a young person removed from a setting returns, which prevents the escalation from being reinforced by the relief.
- **Fidelity of implementation** — The extent to which the specified adult responses were delivered as designed, measured independently of the outcome.
- **Written protocol** — The short, in-room document specifying the target behaviours, the responses, and the exception procedures.

**Key Terms at a Glance (continued)**

- **Staff rehearsal** — The practice, in a training session, of delivering the specified responses to a simulated disruption.
- **Refresher training** — The term-time repetition of the staff training, provided because the skills decay and the staff change.
- **Fidelity check** — The independent observation of whether the intervention was delivered as specified, which converts an unexplained null result into a diagnosable implementation problem.
- **Contingency inventory** — The assessment of what currently follows a behaviour in a setting, for the young person, the peers, and the adults.
- **Class contract** — A term-long written agreement between a class and the school, drafted with the students, in return for specified privileges.
- **Ritualised response** — A predictable adult response to a class-wide behaviour that functions as a signal of significance rather than as a consequence.
- **Function-related intervention team (FRIT)** — A classroom-level system in which a team of staff share the function of a behaviour and respond consistently, increasing the number of adults available to reinforce.
- **Manifestation determination** — The procedural requirement, under disability legislation, that a behaviour resulting in a change of placement be assessed against the possibility that it is a manifestation of a disability.
- **Functional behavioural assessment (FBA)** — The assessment required in many jurisdictions before a change of placement for a student with a disability, and the appropriate basis for a behaviour support plan.
- **Placement change** — A change in the educational setting of a student that triggers the procedural protections of the disability legislation in most jurisdictions.
- **Behavioural contract for a class** — An agreement between a class and the school in which the class commits to specified behaviours in return for specified privileges.
- **Special educational needs and disability code** — The jurisdictional framework that determines the legal status of a behaviour support plan and the procedures that must be followed.
- **Instrumental participation** — A young person's continued involvement in an intervention because it produces a benefit, without the corresponding development; the risk of an unfaded system.

## 12. Chapter Summary

Contingency management in schools and clinics is the most direct application of the operant principles of Chapter 26 to real settings, and its central difficulty is not technical. A school is an organisation of many adults, each of whom responds to a young person's behaviour, and a contingency system is only as strong as its weakest response. The failure mode is predictable: a programme is designed with the class teacher, the teaching assistant is not told, the supply teacher is not told, and on the first day the young person learns that

the system holds on Tuesday and not on Wednesday.

The chapter's first idea is that every setting is already a contingency system, and that the question is never whether to introduce consequences but whether the existing ones serve the young person. The contingency inventory is the assessment tool, and its three common findings are that the problem behaviour is reinforced, that the desired behaviour is unreinforced, and that the adults are inconsistent.

The conditions for appropriateness were stated and the conditions for inappropriateness were stated with them, and the special caution about young people with severe cognitive impairment — for whom the tokens must be understood and the fade correspondingly slower — was included. The token economy was described in its six design decisions and its four implementation requirements, and the class-wide and individual systems were contrasted, with the hybrid recommended. The problems specific to token economies were set out: the contamination of the target behaviour, the peer problem, the staff problem, the incompatibility of token delivery with exclusionary responses, and the risk of promising a reward the school cannot deliver.

Behaviour support plans were described in their elements, and the escalation procedure was given the attention it deserves, because an adult's improvised response to a young person's escalation is the treatment, and because the most common errors — removal without a return condition, variable duration, and return on calming — all inadvertently reinforce the escalation. The chapter noted the legal framework that gives the plan a standing beyond the clinical one, and the practitioner is directed to establish the local regulatory position before writing a plan.

The case of Mr Adeyemi's class illustrated the whole chapter. The referral described three students; the analysis of the data described a single Tuesday afternoon lesson and a thirty-minute unsupervised activity; the functional analysis described a ritualised adult response that functioned as a signal of significance, and the plan that changed the adult's behaviour changed the class. The class contract was, in the end, the smallest part of the intervention.

The implementation section addressed the fidelity problem, the adult who is not on the plan, staff turnover, the young person who is not in the room, and the young person who declines, and the section on evidence noted that the school-based literature is mature and proximal, that fidelity determines the outcome, that training alone is insufficient, and that the classroom-level systems have larger effects than the individual ones because they change the peer ecology.

The ethical analysis in a school setting is sharper than elsewhere because a school is an institution and the peers can see, and the four prohibitions were stated without qualification: never trade a right, never trade attention or warmth, never make the system public if it would humiliate, and do not let the system replace the relationship. The cultural analysis addressed the community-specificity of the available reinforcers, the cultural patterning of public correction, the peer group's valuing of defiance, and the jurisdictional specificity of the discipline framework. The ethical requirements closed the chapter with the question that every review should contain: is this plan still necessary?

## 13. Review and Discussion Questions

**Review and Discussion Questions**

1. Explain the thesis that every setting is already a contingency system.
2. Describe the contingency inventory and state its three common findings.
3. State the three features that make schools and clinics appropriate sites for contingency management.
4. State the six conditions under which contingency management is appropriate, and the four circumstances in which it is not.
5. Explain the special caution required for young people with severe cognitive impairment.
6. State the six design decisions required for a classroom token economy.
7. Describe the five implementation requirements for a token economy, and identify the one most often omitted.
8. Compare the class-wide and the individual token systems, and explain the basis of the recommendation for a hybrid.
9. Explain the contamination of the target behaviour and the role of the fade plan in it.
10. Explain the peer problem, the staff problem, the dismissal problem, and the reward problem in token economies.
11. State the eleven elements of a behaviour support plan.
12. Describe the graduated response procedure and the escalation procedure, and state the three most common errors in them.
13. Explain the significance of the return condition, and describe the effects of the three common errors.
14. Explain the legal and regulatory context of a behaviour support plan, and name the framework in the United States and in the United Kingdom.
15. Describe the form and the advantages of the class contract, and state its three disadvantages.
16. State the limits that apply to a behaviour contract in a school, and explain why each follows from the law.
17. Describe the case of Mr Adeyemi's class and state the two features of it that generalise.
18. Explain the four implementation problems: fidelity, the adult not on the plan, turnover, and the young person not in the room.
19. Explain the three possible reasons for a young person's refusal to participate, and the appropriate response to each.
20. Summarise the status of the evidence for classroom-level interventions, token economies, function-based support plans, and contingency management for substance use.

**Review and Discussion Questions (continued)**

21. State the three implementation findings from the evidence, and explain why they are more useful to a practitioner than the outcome studies.
22. State the four limitations of the school-based evidence base.
23. State the five strengths and the five limitations of contingency management in institutions.
24. State the four prohibitions that apply to a school-based system, and explain the reasoning for each.
25. State the three cultural considerations that bear on the design of a school-based system.
26. State the eight ethical requirements for contingency management in a school, and explain the significance of the requirement that every plan have an end.

## 14. Practice Activities

**Practice and Application**

### Activity 28.1 — The Contingency Inventory (90 minutes, field-based)

In a placement, choose one behaviour that concerns the adults in the setting but that the referral describes in general terms. Complete the contingency inventory for it: what happens immediately before, what happens immediately after, for the young person, the peers, and the adults, and what the young person's alternative produces. Write the inventory in one page. Then write the single sentence stating what the behaviour appears to accomplish. Most students find that the behaviour is being reinforced by something nobody intended, and the finding is almost always more actionable than the behaviour.

### Activity 28.2 — Designing a Token Economy (90 minutes, individual)

Design a classroom token economy for a real secondary class. Specify the three target behaviours, the token, the backup reinforcers, the schedule, the exchange procedure, the response cost, and the fade plan. Then write the protocol as it would appear on the desk, in no more than twenty lines. The twenty-line constraint is the discipline, and most first drafts are twice as long as they should be and cannot be used at the front of a room.

### Activity 28.3 — The Fidelity Simulation (60 minutes, small group)

In groups of four, one student plays the teaching assistant, one the subject teacher, one the young person, and one the practitioner observing. The practitioner describes a plan and the two staff members respond to a simulated disruption in the way they think appropriate, without further instruction. The practitioner then checks the response against the written protocol. The exercise is uncomfortable and it is the most accurate simulation of the implementation problem that the book contains, and it consistently shows that the discrepancies are not in the staff's motivation but in their knowledge of what the plan requires.

### Activity 28.4 — Redressing a Plan (60 minutes, individual)

Take a behaviour support plan from a placement, or construct one, and audit it against five questions: does it condition any right on behaviour; does it use adult attention or approval as a reward; is it visible to peers in a way that would humiliate a particular young person; does it specify what happens with the adults who are not on the plan; and does it have a stated end? For each failure, write the revision. Most plans fail the first three, and the revisions are the practical work of the chapter.

## 15. Annotated Reading Pathways

**For the design.** Read Azrin and Lanza (1976) for the token economy, and read the classroom-level systems literature for the function-related intervention team and its relatives. The classroom-level material is the most direct guide to the class-wide approach and it has the strongest effect sizes.

**For the implementation.** Read the fidelity literature, and read one study that measured implementation and reported a null result. The contrast with a study that measured implementation and reported a large effect is the most useful pair of readings in the chapter.

**For the law.** Read the local behaviour and disability framework before writing any plan, and read the manifestation determination guidance. This is not optional reading and it takes an afternoon.

**For the evidence.** Read the school-based reviews and the classroom-level meta-analyses, and read the substance use contingency management literature, which is the most methodologically mature part of the applied evidence base.

**For the ethics.** Read the critical literature on reward-based practice in schools and on the historical use of token economies in institutions, and read the disability rights literature on the protections of students with behaviour difficulties. The combination of the technical and the critical literature is the preparation for writing a plan that a school will use and a family will accept.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Contingency Management in Schools and Clinics** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is token systems, behaviour contracts, and the negotiated restructuring of reinforcement in real settings. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is functional analysis, learning history, contingencies, mastery, and measurable behaviour change. The mechanism to keep in view is how antecedents, consequences, skills, avoidance, and environmental design select and maintain behaviour. The characteristic professional risk is using control without assent, reinforcing compliance rather than wellbeing, or ignoring the meaning and function of behaviour. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in classrooms, homes, clinics, and other real environments where behaviour occurs, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the

next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Tunde is fifteen and is seen in a community adolescent clinic for grief following a major family change. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Tunde's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Tunde explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on functional analysis, learning history, contingencies, mastery, and measurable behaviour change. The first intervention is deliberately modest. Tunde chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Tunde has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Tunde can describe the pattern without

adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?

- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Contingency Management in Schools and Clinics

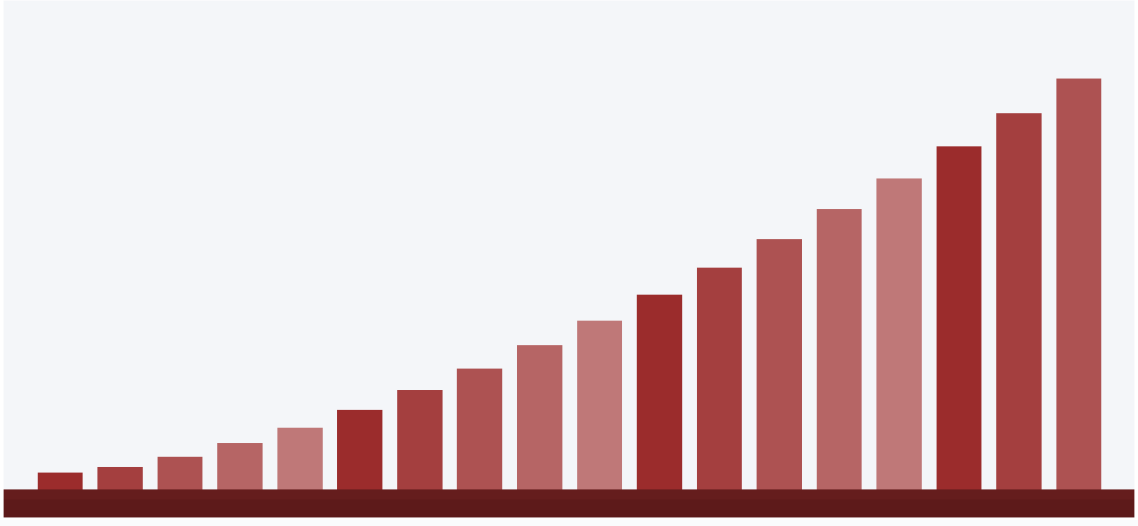
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Contingency Management in Schools and Clinics** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Contingency Management in Schools and Clinics** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Contingency Management in Schools and Clinics**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Contingency Management in Schools and Clinics to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 29

# Functional Analysis of Self-Injurious and Aggressive Behaviour

Safety-oriented assessment and intervention with behaviour that is harmful or dangerous.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the safety-first framework that governs work with self-injurious and aggressive behaviour.
- Describe the epidemiology, the range of presentation, and the differential diagnosis of self-injury and aggression in children and adolescents.
- Describe the functional analysis of self-injurious behaviour, including the assessment of the antecedents, the behaviours, and the medical factors.
- Apply the four functional classes and the setting demands to the analysis of self-injury and aggression.
- Describe the safety interventions for self-injury and aggression, including the physical, environmental, and relational components.
- Describe the treatment approaches for each function, and state the specific treatment of aggression maintained by escape and by attention.
- Explain the standards of care and the documentation required for work with this behaviour.
- Critically evaluate the cultural and ethical dimensions of work with dangerous behaviour, including the questions of restraint, of restrictive intervention, and of the young person's dignity.

## Chapter Overview

This chapter concerns behaviour that can kill or permanently injure a young person, and it is written with a different set of conventions from the rest of the book. There is no discussion here of whether the behaviour should change. The behaviour must change. The clinical questions are about what the behaviour is accomplishing, what the safest intervention is, and what treatment will be effective and safe in the long run.

Two behavioural presentations are treated together because they frequently co-occur, because the analysis is parallel, and because the young people who present with one frequently present with the other later. They are, however, distinct in their consequences, their risk profiles, and their treatment implications, and the chapter keeps them distinct.

The safety framework has four elements and it should be stated at the outset because it governs everything else in the chapter. **The safety of the young person comes first and is not contingent on the assessment being complete. The least restrictive effective procedure governs the choice of intervention. The treatment of the behaviour is not the treatment of the condition**, and a young person whose self-injury is a symptom of a disorder requires the treatment of the disorder, not only the management of the injury. And **the intervention must be accompanied by a plan for the young person's dignity**, because the interventions that protect a young person from harm are frequently experienced as punishments, and the young person who experiences them as punishments will not tell anyone when the next episode is building.

A working knowledge of this material is not optional for a practitioner who works with young people, and a working knowledge of the ethical framework is not optional either, because the interventions in this area are the ones in which a practitioner's decisions can be challenged and reviewed.

## 1. Historical Context

## 1.1 From the asylum to the institution

Self-injurious behaviour has a long and grim history in the institutional treatment of people with learning disabilities and mental illness. The nineteenth-century practice of "moral treatment" included elaborate mechanical devices designed to prevent self-injury, and the twentieth century added the padded cell, the restraint, and the surgical intervention for the self-injurious behaviour of a small number of people with a severe genetic condition. The literature is a record of a systematic failure to understand the behaviour before trying to control it, and it is a useful reminder that an unexplained behaviour is usually treated harshly.

## 1.2 The functional analysis of self-injury

The decisive development was the work of Iwata and colleagues from the 1980s, and its central finding was methodological. Before that work, self-injury was treated on the assumption that it served an unknown purpose, and the intervention was a physical one. Iwata's group demonstrated that the behaviour could be analysed experimentally in the same way as any other behaviour: by manipulating the consequences across conditions and observing whether the behaviour changed.

The findings were published in 1982 and 1994 and they are the foundation of everything that followed. Self-injury in the population studied was overwhelmingly maintained by **automatic reinforcement** — the behaviour produced its own sensory consequence — and, in the remainder, by escape from demands and by attention. The proportion of cases in which the behaviour was maintained by automatic reinforcement was much higher than had been assumed, and this finding changed practice fundamentally, because it meant that a young person whose self-injury is automatically maintained requires a very different plan from one whose self-injury is escape-maintained.

The therapeutic consequence of the automatic reinforcement finding is the treatment of the sensory consequences themselves, through the pharmacological management of the underlying condition, through a programme of alternative sensory stimulation, and through the extinction of the behaviour — and the practical consequence is that the "treatment as usual" of self-injury, which was containment, is largely ineffective, because containment removes the behaviour but does not remove the maintaining contingency.

## 1.3 The function of aggression

The functional analysis of aggression developed in parallel, with the critical contribution of the studies of aggression maintained by **attention** and by **escape**, and the demonstration that a substantial proportion of physical aggression in young people with learning disabilities is escape-maintained, is a request for help, or is the only available form of communication, and not a desire to hurt.

This finding has had a profound effect on practice, because the response to a young person's aggression in most settings is escalation, and escalation is exactly what maintains the behaviour.

## 1.4 The regulatory history

Work with this behaviour in the United States is now subject to a dense regulatory framework, and a practitioner must know it before working in a setting where it applies. The relevant framework includes the federal protections for individuals with disabilities, including the requirement of a functional behavioural assessment before a change of placement and the manifestation determination procedure; the prohibitions on the use of seclusion and of physical restraint as written in the federal regulations, and the conditions under which they may be used; the requirements of the Americans with Disabilities Act in relation to the

modification of policies and practices; and the state-level licensing standards for residential and inpatient settings, which vary considerably and are frequently more specific than the federal rules.

The practical requirement is straightforward and should be stated in the chapter's conclusions: a practitioner working with this behaviour in a regulated setting is implementing the plan of a team, under supervision, within a documented protocol, and every element of the plan that touches the young person's body, liberty, or dignity is subject to review.

# 2. Safety

## 2.1 The hierarchy

The safety hierarchy for work with dangerous behaviour is ordered, and the order is not negotiable.

**Level 1: Immediate physical safety.** The prevention of imminent harm to the young person or to others. This is the only consideration that overrides every other consideration, including the young person's assent, the family's preference, and the practitioner's own discomfort.

**Level 2: Medical assessment.** The determination that the injury or the aggression is not a medical emergency requiring other care. A young person who is self-injuring may have an undiagnosed condition contributing to it, and a young person who is aggressive may be in pain, or have a neurological condition, or be in a state of delirium, and in each of these cases the behavioural analysis is the wrong frame entirely.

**Level 3: The functional assessment.** The determination of what the behaviour is accomplishing. This cannot be conducted while the young person is in acute danger, and a plan that requires the assessment to be completed before the safety interventions are in place is a plan that will fail.

**Level 4: The treatment.** The long-term reduction of the behaviour and the increase of the young person's repertoire.

## 2.2 The safety plan for self-injury

A safety plan for self-injury has five components, and it is written down, shared with everyone who works with the young person, and rehearsed.

**The functional prediction.** The circumstances in which the behaviour is likely, stated specifically enough to be recognisable, and derived from the functional analysis if it has been conducted, and from the pattern of previous episodes if it has not.

**The response to the early indicators.** The physiological and behavioural precursors — a change in breathing, a change in the pattern of movement, the sudden quietness, the change of tone — and what the adult should do at that point. The early indicators are specific to the individual and are usually known only from careful observation, and they are the most valuable single piece of information in a safety plan.

**The response to the behaviour.** The procedure, specified in advance, and practised, and consistent across all adults. The procedure should specify the physical approach, the words used, the position of the adult, and what is done if the young person resists.

**The provision of the alternative.** The sensory input or the break or the help that the analysis indicates the young person is seeking, available at the moment of the early indicators and not only after the behaviour.

**The medical and the psychological response after an episode.** The physical care, the documentation, the review, and the decision about whether the episode changes the plan.

## 2.3 The safety plan for aggression

The safety plan for aggression has five components as well, and the first of them is different in kind.

**The identification of the target of the aggression.** Who is at risk: the young person, other young people, staff, family, or the wider community. The risk assessment should be explicit about the worst credible outcome, and the practitioner should be willing to state that a young person has a realistic potential to kill, because the risk assessment is useless if it understates the risk.

**The identification of the precursors**, as for self-injury, with the addition of the situational variables: the time of day, the staffing level, the noise level, the presence of a specific peer, the state of the young person's medication.

**The avoidance and the environmental modification.** The changes to the environment that reduce the likelihood of the episode — the change of route, the reduction of noise, the staffing adjustment, the removal of the trigger from the space.

**The response to the behaviour**, specified and rehearsed, and including the specification of what the adult does when the young person is escalating, which is usually the most important part of the plan and the part most often improvised.

**The plan for the aftermath**, including the repair of any relationship damaged by the episode, which is a clinical task and not a courtesy. A young person who has just attacked a member of staff and is then treated as a danger for a month has learned that violence is the only route to significance, and the plan for the aftermath is the part of the plan that prevents the next escalation.

## 2.4 The role of restrictive interventions

Restrictive interventions — physical restraint, seclusion, and the chemical equivalents — are the most fraught part of this work, and the professional position should be stated plainly.

They are **last-resort interventions**, used only when the young person poses an imminent danger to themselves or to others, and when less restrictive interventions have been tried and have failed, and when the intervention is used for the shortest possible time, and with the monitoring and the documentation and the review that the law requires.

They are **more likely to cause harm than to prevent it** in the cases in which they are used most often, because they are used with the young people who are most distressed and least responsive, and the restraint of a distressed young person is itself a trigger, and it frequently produces the aggression it is intended to prevent.

They are **subject to oversight**, and a practitioner who uses them without a documented protocol, without the training, and without the review is not practising within the professional standard, whatever the local law happens to permit.

And they are, in the clinical literature, associated with higher rates of injury to the staff, higher rates of injury to the young person, higher rates of subsequent aggression, and worse therapeutic outcomes. This is not an argument against their use in a genuine emergency; it is an argument for the seriousness with which they should be used, and for the institutional responsibility to design the environment so that they are

needed less.

# 3. Presentation and Diagnosis

## 3.1 Self-injurious behaviour

Self-injury in children and adolescents presents in a wide range of forms and with a wide range of functions. The forms include: skin picking, scratching, and cutting; head banging and hitting; eye poking; hair pulling; and the more severe forms involving burning or the ingestion of objects. The frequency ranges from occasional and low harm to several times daily and severely injurious.

The differential diagnosis is wide and includes: the stereotyped movement disorders of the autism spectrum; the self-injury associated with specific genetic syndromes, notably Lesch–Nyhan syndrome, Smith–Magenis syndrome, and Cornelia de Lange syndrome; the self-injury associated with a psychotic disorder; the self-injury associated with a trauma history, including the self-harm behaviours of a young person who is being abused; the self-injury associated with a mood disorder; and the self-injury associated with a communication impairment or with an unmet need.

The differential has direct clinical consequences, because the treatment of the self-injury follows the diagnosis. Self-injury in a young person with a genetic syndrome with a characteristic neurochemical profile may be substantially responsive to pharmacological management, and the behavioural plan is then an adjunct rather than the treatment. Self-injury that is a symptom of psychosis requires the treatment of the psychosis. Self-injury that is a response to abuse requires the protection of the young person, not the extinction of the symptom.

## 3.2 Aggression

Aggression likewise presents in a range of forms: verbal aggression and threats; the destruction of property; physical aggression towards peers, towards adults, and towards animals; and the more severe forms of severe violence.

The differential diagnosis includes: the impulsivity and irritability of a mood disorder, including the irritability of a depressive episode, which is a presentation that is frequently missed in adolescents and which is often the correct diagnosis of a young person referred for aggression; the impulsivity of a neurodevelopmental condition; the psychosis, in which aggression may be a response to persecutory beliefs; the disinhibition of a substance; the dysregulation of a trauma response; the learned pattern of a young person who has been in an environment where aggression was the only effective response; and the communication of a young person who has no other way to express a need.

The diagnosis of the mood disorder is the one most often missed and it is worth dwelling on. An adolescent with a depressive episode, with the irritability that is its characteristic presentation in adolescence, is frequently referred to a behaviour service because the irritability presents as aggression. Treating the aggression behaviourally, without treating the depression, will fail, and it will fail in a way that increases the young person's shame.

## 3.3 The assessment

The assessment of dangerous behaviour is comprehensive, and its components are as follows.

**A full history**, including the developmental history, the medical history, the medication history, the trauma history, the family history, the educational history, and the history of previous interventions and their outcomes.

**A physical examination and a medical review**, including a review of the medication, a review of the pain, a review of the sleep, a review of the seizures, and a review of the sensory environment. A young person in pain is an aggressive young person, and this is not a figure of speech.

**The functional analysis**, which is the subject of Sections 4 and 5.

**A risk assessment**, which is a separate document from the functional analysis and has a separate structure: the identification of the risk, the likelihood, the severity, the protective factors, the current level of risk, and the review date. The risk assessment should be written in language that a court, a family, and a young person could each read and understand.

**A functional assessment of the environment**, which examines the antecedents in the physical setting: the noise, the crowding, the lighting, the temperature, the seating, the transitions, the staff-to-young-person ratios, the schedule.

**A developmental assessment**, because the meaning of the behaviour and the feasible alternatives are both developmental facts.

**An assessment of the young person's own view.** A young person who is aggressive has usually been asked about it many times and has usually found the question useless, and the practitioner should approach it differently, with attention to what the young person wants, what makes the behaviour difficult to stop, and what the young person has tried.

# 4. The Functional Analysis of Self-Injury

## 4.1 The stages

The functional analysis of self-injury proceeds in a defined order, and the order reflects the safety hierarchy.

**Stage 1: Safety and medical.** The safety plan is in place, the medical assessment is complete, and the physical management of the injury is available.

**Stage 2: Descriptive assessment.** A structured record of the episodes, their antecedents, their consequences, the settings, the times, the frequency, the severity, and the injury sustained. The descriptive assessment is the foundation of the experimental analysis, and it is also the point at which the pattern of the early indicators is discovered, which is the most clinically valuable output of the whole exercise.

**Stage 3: Experimental analysis.** The manipulation of the consequences across conditions.

**Stage 4: The treatment plan**, specified in terms of the function.

## 4.2 The experimental analysis

The analysis of self-injury uses a set of conditions, each of which is designed to isolate a particular consequence. The conditions run in blocks, typically five to fifteen minutes, in a treatment room or a ward, with the young person observed and the behaviour recorded.

**The alone condition** — the young person is alone in the room, with an observer. The behaviour that persists in this condition is maintained by its own consequences, that is, automatically.

**The attention condition** — the observer attends to the young person, and the attention is delivered in the way that the descriptive assessment suggests the young person finds reinforcing, which is usually the way in which the behaviour has previously obtained attention. The behaviour that increases in this condition is maintained by attention.

**The demand condition** — demands are presented, and the opportunity to escape or to take a break is contingent on the behaviour. The behaviour that increases under demands is escape-maintained.

**The play condition** — the environment is arranged to be engaging and the observer does not attend to the self-injury. The behaviour that decreases in this condition is, by elimination, automatically maintained.

**The control conditions** — the condition in which the consequence of interest is delivered non-contingently, which is the control for the possibility that the mere presence of the consequence is maintaining the behaviour.

**The social control condition** — the young person is observed with another person present who does not respond to the behaviour, which distinguishes the behaviour that requires an audience from the behaviour that does not.

The interpretation follows the logic of Chapter 24. The behaviour that is high in the alone and play conditions and low in the attention and demand conditions is automatically maintained. The behaviour that is high in the attention condition is attention-maintained. The behaviour that is high in the demand condition is escape-maintained. A great many cases show more than one pattern, and the analysis then describes a behaviour with more than one function, which requires a treatment plan for each function.

### 4.3 The interpretation

The interpretation of the analysis has three parts: the function, the setting demands, and the establishing and maintaining conditions.

**The function** is what the behaviour produces: sensory input, escape from a demand, escape from social interaction, or attention from others.

**The setting demands** are the conditions under which the behaviour occurs: automatic, attention, escape, or the combinations.

**The establishing conditions** are how the behaviour came to be performed, and they are usually historical — a period of illness in which the behaviour produced an analgesic effect, a period of abuse in which it produced a change in the perpetrator's behaviour, a period of communication impairment in which it was the only effective signal.

The establishing conditions matter because they are the reason the behaviour is "stuck", and because they indicate that the treatment must address something other than the current contingencies alone.

## 5. The Functional Analysis of Aggression

### 5.1 The procedure

The analysis of aggression follows the same structure, with three modifications.

**The analysis is conducted in the settings in which the aggression occurs**, whenever this is possible, because the contingencies in a ward and the contingencies in a classroom are different, and the behaviour is

often maintained by different consequences in each.

**The observation is of the antecedents with particular care**, because the predictors of serious aggression in a setting are often specific and physical: the noise, the crowding, the time of day, the specific peer, the transition, the medication state, the pain.

**The consequences are examined with attention to the adult responses**, because the adult response to the escalation is usually the maintaining contingency. The analysis includes a record of what the adult did immediately after the aggression, and the analysis of the escalation sequence is usually the most informative single component.

## 5.2 The four patterns and their treatments

**Attention-maintained aggression.** The aggression reliably produces adult attention, and the treatment is differential reinforcement of the appropriate behaviour and the planned ignoring of the aggression, and — this is the difficult part — the systematic change of the adults' response so that the escalation no longer produces attention. The treatment also requires the adults to provide the attention at other times, so that the young person is not deprived of it altogether.

**Escape-maintained aggression.** The aggression reliably terminates a demand. The treatment is differential reinforcement of compliance, the planned ignoring of the escalation, the reduction of the demands, and the teaching of an alternative request for help or break. The treatment must include a clear plan for what the adults do when the escalation occurs, because the escalation is the behaviour that is working.

**Automatically maintained aggression.** The aggression produces its own sensory consequence, which is uncommon in aggression as distinct from self-injury, and it occurs most often in young people with a neurodevelopmental condition and a sensory processing difference. The treatment is the management of the sensory environment and the pharmacological treatment of the underlying condition.

**Multiple functions.** A great many young people present with aggression maintained by both escape and attention, and the treatment must address both, and the differential reinforcement of compliance with the extinction of escalation is the core of the plan in either case.

## 5.3 The treatment of the escape-maintained case in detail

Because the escape-maintained case is both the most common and the most reliably treated, it is worth setting out the procedure in the detail in which it should be implemented.

**Reduce the demands.** The demands that the young person is escaping are identified and broken down into smaller steps, and the young person is taught the steps. A young person who cannot do the task will escape the task, and the correct intervention is the teaching of the task.

**Reinforce compliance.** Every instance of compliance is reinforced, immediately, with something small and frequent. The reinforcement must be more immediate and more frequent than the escape it is intended to replace, and the schedule must be dense at the beginning.

**Do not respond to the escalation.** The escalation is ignored — genuinely ignored, with no eye contact, no speech, no raised voice, and no attempt to calm the young person. This is difficult for adults, and it is the part of the plan most likely to fail, and it is the part most in need of training and rehearsal.

**Provide the alternative.** A signal for help, a break card, a specified call to a staff member, which the young person can use, which is trained, and which is honoured immediately when used. The alternative must be

available at the same time as the demand, and it must be a real alternative and not a slower route to the same escape, because a young person who can ask for a break in thirty seconds will use it.

**Expect the burst.** The behaviour will increase before it decreases, and the practitioner should tell the young person this in advance, and should not interpret the increase as a failure of the plan.

**Fidelity.** The adults' responses must be consistent, and the fidelity of the response to the escalation is the variable that determines the outcome.

## 7. Case Illustration: The Young Person Who Hurt Himself in the Bathroom

**Presentation.** Marcus is fifteen, and he lives in a residential placement. He has a diagnosis of a neurodevelopmental condition and a history of placement breakdown. He has a behaviour of biting his own forearm, most often in the bathroom, most often in the late afternoon, and it has been increasing over the last six weeks. The injury on the day of the referral was severe enough to need a hospital assessment, and the placement manager is asking whether the placement can continue.

This is the situation in which a practitioner must be extremely careful about the sequence of events, because the pressure is to produce a plan immediately and the plan that gets produced under this pressure is usually a containment plan that will not work.

**Step 1: safety.** The safety plan is written on the first day, before anything else, and it is short and it is specific. It names the early indicators — and these come from the staff, who have been the ones watching: a particular stillness, the sudden interest in the bathroom, the way he stops mid-sentence, a hand going to his pocket. It specifies who goes to him, what they say, and what they do. It specifies the response to the behaviour itself, which is the removal of the identified object — in this case, it is a modification of his clothing, because the biting has been found to occur when his forearm is bare and the arm is exposed, and the clothing change is a modification that costs him nothing in dignity. And it specifies the provision of the alternative: a weighted item that he takes with him and that he has already identified as calming, which is permitted and encouraged, and which is the thing that has been removed from him in the last placement.

**Step 2: medical.** The medical review is the second step, and it is not a formality. It establishes a full medication review, and it establishes that Marcus's last medication review was eleven months ago, which is itself a finding. It establishes that he has been having significant headaches, which his presentation team had not known, and which are being treated. It establishes that his sleep has been disrupted by the placement's night-time routine, and that he is not eating properly, and that both have changed in the last six weeks, which is the period over which the behaviour has increased. A change in the behaviour over a defined period always indicates a change in the conditions, and the medical review is where the change is found.

**Step 3: the functional assessment.** The descriptive assessment comes next, and it is done with the staff rather than in a clinic, because the behaviour occurs in the placement.

The ABC record is revealing. The antecedents are consistent: late afternoon, the bathroom, alone, and — in the last six weeks — the arrival of a specific member of staff who works the late shift and who has come from a different placement with a very different approach, and who is loud, and who rearranges the bathroom. The consequences are also consistent: the bathroom door is closed, and the young person is alone, and the physical sensation of the bite is a strong stimulus, and the bite is followed by a reduction in the emotional state that the staff describe as "settled" and that Marcus describes, much later, as "quieter".

The pattern is that the behaviour is most likely in the late afternoon, that it has increased since a change of staff, and that it is followed by a marked reduction in the young person's distress. That pattern is consistent with automatic reinforcement — the behaviour produces a sensory and affective consequence — and it is also consistent with escape, because being alone in the bathroom is a relief after a shift with a loud staff member.

**Step 4: the experimental analysis.** The analysis is conducted in a structured way in the placement's quiet room. The conditions are: alone; play; attention; demand; and the corresponding controls. The results are

clear and they are not the results the placement team expected.

The behaviour occurs at a high rate in the alone condition, at a low rate in the play condition, at a low rate in the attention condition, and at a low rate in the demand condition. The behaviour is **automatically maintained**, and the placement team's expectation — that the behaviour was a bid for attention, which was the reason their previous placements had escalated to restraint — was wrong.

**The establishing conditions.** The behaviour is not new; it existed, more mildly, in the previous placement, and it was described there as attention-seeking. The question of what it was originally for is not answerable from the records, and the honest answer is recorded.

**The treatment.** The plan has four elements.

*The medical and environmental work first.* The headaches are treated. The sleep and the eating are addressed, because a young person in pain and in a state of sleep deprivation is more likely to self-injure, and because these were the changes that preceded the increase. The loud staff member is consulted — with a discussion about the approach rather than about the young person, and with the specific request that the bathroom not be rearranged during the late shift, which is a small change with a large effect.

*The modification of the environment.* The weighted item is returned, and its use is not treated as a problem. The bathroom door is not closed on him; the door has a gap and he is visible. The clothing modification is made permanent for the late afternoon, and the young person chooses the clothing, and the choice is the point.

*The differential reinforcement of the alternative.* The alternative behaviour — going to the quiet room with the weighted item when the distress builds — is reinforced immediately, and the reinforcement is frequent and small, and the adult response to the alternative is warm and specific.

*The extinction of the behaviour, with a safety overlay.* The behaviour is placed on extinction: the consequence that has been maintaining it, which is the quiet and the relief, is no longer delivered immediately, and the bathroom is no longer available as a place of immediate relief, because the consequence of the behaviour is now the intervention of the staff, which is the safety response. This is the step that is most likely to produce an increase in the first week, and the staff are told so in advance, and the safety response is specified in the plan so that the increase does not become a crisis.

**The outcome.** The behaviour decreases over approximately six weeks, with a consistent pattern of a slight increase at the point of each staff change and a rapid decrease once the new staff member is established. Marcus's placement continues. The medication review is now monthly. The sleep and the eating have improved.

**The outcome that the plan was not designed to produce.** Marcus's own account, offered in a session in the eighth week, is that the biting was "the only way to make it stop" — and the "it" is the noise and the rushing and the being told what to do. The behavioural analysis found the automatic consequence and the treatment addressed it, and the young person's own account found the escape and named it precisely. Both were correct, and the plan that had been built only on the experimental analysis would have addressed the automatic function and left the escape function intact, and the behaviour would have persisted in a modified form.

The case is therefore an argument for the method described in Chapter 24: the young person's own account is data, and it should be gathered as early as possible, and it is not an alternative to the experimental analysis but a supplement to it.

# 8. Evidence and Research Support

## 8.1 The status of the evidence

The evidence for the treatment of self-injury and aggression is more methodologically mature than the evidence for most of this book, and this is because the behaviour is severe enough, and the outcomes are severe enough, and the field has invested heavily in the experimental analysis that produces reliable individual treatment plans.

**The functional analysis of self-injury is a well-established procedure with a large literature.** The proportion of cases in which the behaviour is maintained by automatic reinforcement is consistently reported to be high, and this is the single most clinically consequential finding in the field.

**Function-based treatment plans are more effective than non-function-based plans**, and this is the finding that the whole approach rests on.

**Differential reinforcement, differential reinforcement of compliance, and planned ignoring are effective for the escape- and attention-maintained cases**, and the evidence for the treatment of aggression maintained by escape is good.

**Pharmacological management is effective for a subset of self-injury**, particularly in the specific genetic syndromes, and it is essential in those cases. The clinician who works only behaviourally will miss the treatable neurochemical cases.

**The evidence for the environmental and medical components is weaker**, largely because these are difficult to evaluate in controlled trials, and the field's assessment of them rests on the clinical logic that a change in the antecedents precedes a change in the behaviour.

**The evidence on restrictive interventions is substantial and it is consistently negative**, with the studies showing higher rates of injury, higher rates of subsequent aggression, and worse outcomes. This is the point at which the evidence and the ethics converge: the interventions that are used most often in the settings where this work happens are the interventions with the worst evidence and the greatest risk.

## 8.2 Limitations of the evidence

**The samples are small and highly selected**, and they are drawn disproportionately from the most severe cases, who are the least representative of the population.

**The outcome measures are almost exclusively the frequency of the behaviour**, and the measures of the young person's quality of life, of their sense of dignity, of the family relationships, and of the durability of the change in naturalistic settings are much less systematically reported.

**The designs are the single-case experimental designs of Chapter 24**, and although they are rigorous, they are vulnerable to the reactivity of the participants and to the observer expectancy that the field has worked hard to address.

**The long-term outcomes are under-researched**, and there is a serious question about what happens to the young people whose behaviour has been reduced: what becomes of them, what is the placement plan, and what is the plan for the transition to adulthood.

**The literature is dominated by English-language research in North American and European settings**, and the cultural specificities of the settings in which this work happens — the tolerance for certain behaviours in a community, the family's understanding of the behaviour, the role of the extended family —

are under-examined.

# 9. Strengths and Limitations of the Functional Approach to Dangerous Behaviour

## 9.1 Strengths

**It is the only approach with a demonstrated mechanism.** The treatment is targeted at the contingency that maintains the behaviour, and when the contingency is identified and altered, the behaviour changes.

**It is the only approach that produces a differentiated plan.** A young person whose self-injury is automatically maintained and a young person whose aggression is escape-maintained receive entirely different plans, and the analysis is what makes the difference visible.

**It reduces the reliance on the most restrictive interventions**, because the analysis identifies the environmental changes that remove the need for them.

**It produces a written, teachable, and auditable plan**, which is what a team, a family, and a regulator can all work with.

**It treats the young person's behaviour as information rather than as a moral failure**, which is the foundation of every intervention in this chapter.

## 9.2 Limitations

**The analysis is slow and the behaviour is urgent.** The experimental analysis of self-injury takes days to weeks, and in the interval the young person is at risk. The safety-first framework is the solution, and it is an imperfect one.

**The analysis requires a stable setting with trained staff**, and the population in which this work is needed is characterised by instability and turnover. A plan written in one placement is frequently irrelevant in the next.

**The analysis can be wrong, and it can be wrong in a way that is hard to detect.** A behaviour that is maintained by several functions may appear to respond to one, and the response may be partial.

**The treatment of the behaviour is not the treatment of the young person.** A young person whose self-injury is a symptom of psychosis requires the treatment of the psychosis, and a young person whose aggression is a symptom of a depressive episode requires the treatment of the depression, and the behavioural plan is an adjunct. The functional approach is powerful precisely because it can be applied to behaviour that has no other treatment, and this is also its limitation, because it can be applied to behaviour that does have one.

**The approach requires an institutional commitment that many settings do not have.** The analysis is only as good as the environment in which the plan is implemented, and a placement that wants the behaviour to stop without wanting to change its environment will produce a plan that will fail.

# 10. Cultural and Ethical Considerations

## 10.1 The cultural frame of dangerous behaviour

**The definition of dangerous is culturally and legally specific.** What is considered a serious risk, what is considered an acceptable level of self-injury, and what the state is willing to do about it vary considerably between jurisdictions and between communities, and a practitioner must know the local legal framework, the local threshold for intervention, and the local understanding of the young person and the family.

**The meaning of the behaviour is culturally framed.** A young person's aggression towards a family member may be read in one community as a symptom, in another as a discipline that has been applied to her, and in a third as a form of protest. The practitioner who applies a functional analysis without asking the family what they understand the behaviour to be doing will design a plan that is fighting the family's understanding.

**The family's role is culturally variable.** In some settings the family is the treatment team; in others, the family is a source of additional risk; and in a substantial number of cases the family is the placement that the behaviour has already destroyed, and the practitioner must be able to work with a family that has been told that their child is dangerous.

**The stigma attached to the behaviour is severe and it is socially reproduced.** A young person with a record of violent behaviour or of self-harm is excluded from ordinary opportunities long after the behaviour has stopped, and the practitioner who reduces the behaviour and does nothing about the consequences of the record has delivered a treatment with a short-term benefit and a long-term harm.

## 10.2 Ethical requirements

**The safety of the young person is the first consideration**, and the safety of others is the second, and both are treated as absolute in the immediate term. The rest of the ethical requirements operate within that frame.

**The least restrictive effective procedure.** Every plan should be able to answer the question of what alternatives were considered and why they were rejected, and the answer should be written down. This is both an ethical and a legal requirement in most jurisdictions.

**Proportionality and the documentation of restrictive interventions.** Every use of restraint, of seclusion, and of any restrictive medication must be documented with the specific circumstances, the duration, the less restrictive options that were attempted, the injuries sustained by anyone, and the review that followed. A plan that does not document these is a plan that cannot be defended.

**The young person's dignity.** The interventions that protect a young person can be experienced as punishment, and the practitioner should name this in the plan and design against it. Three specific practices help: the young person is told what will happen before it happens, and the telling is not conditional on their cooperation; the interventions are applied with as little force and as little audience as possible; and the young person is involved in the review of the plan, which is the single most effective protection against the accumulation of unexamined restrictions.

**The right to be heard.** The young person has a right to be consulted about the plan, and to have their account of the behaviour recorded, and — in most jurisdictions — a right to complain about the interventions used. The presence of a complaints route in the plan is itself a protective practice.

**The right to the least restrictive environment.** The plan should specify the target environment, and the goal should be stated as the young person's return to the least restrictive setting in which the behaviour can be managed, with the steps and the criteria. A plan that has no stated goal of restoration is a plan of permanent containment.

**Family inclusion.** The family should be included in the plan, supported, and given something to do, and the support should be practical. The alternative is a family that is excluded from the plan and is then unable to support it.

**Coordination of the multidisciplinary team.** The plan should be developed by a team, reviewed by a team, and shared with the family, and a practitioner working alone in this area is working outside the professional standard.

**Avoidance of the instrumentalisation of the young person.** A young person whose dangerous behaviour makes them valuable as a demonstration, as a training case, or as a research participant has been abused, and the field's history contains a number of such episodes.

## 11. Key Terms

### Key Terms at a Glance

- **Self-injurious behaviour (SIB)** — Behaviour in which a person inflicts physical harm on themselves, including skin picking, scratching, cutting, head banging, eye poking, and hair pulling.
- **Aggression** — Behaviour intended to cause harm, damage, or intimidation to another person or to property; including verbal aggression, destruction, and physical violence.
- **The safety-first framework** — The ordering of the clinical work in which immediate safety precedes medical assessment, which precedes the functional assessment, which precedes the treatment.
- **Safety plan** — The written, shared, and rehearsed specification of the predictors of the behaviour, the response at each stage, the provision of the alternative, and the response after an episode.
- **Early indicators** — The physiological and behavioural precursors of an episode, individual to the young person, and usually the most valuable single output of the descriptive assessment.
- **Functional analysis of self-injury** — The experimental determination of the consequence that maintains the behaviour, using alone, play, attention, demand, and control conditions.
- **The alone condition** — The experimental condition in which the young person is alone with an observer, used to identify automatically maintained behaviour.
- **The play condition** — The condition in which the environment is arranged to be engaging and the behaviour is not attended to, used as the control for automatic maintenance.
- **The attention condition** — The condition in which attention is delivered contingently on the behaviour, used to identify attention-maintained behaviour.
- **The demand condition** — The condition in which demands are made and escape is contingent on the behaviour, used to identify escape-maintained behaviour.
- **The control condition** — The condition in which the consequence of interest is delivered non-contingently, controlling for the presence of the consequence rather than its contingency.
- **Automatic reinforcement** — Maintenance of a behaviour by its own sensory or affective consequences, without reference to the social environment; the most common function of self-injury.
- **Automatically maintained behaviour** — Behaviour that persists in the alone and play conditions and is not maintained by a social consequence.
- **Escape-maintained aggression** — Aggression that reliably terminates or postpones a demand; the most common function of aggression in young people and the most reliably treated.

### Key Terms at a Glance (continued)

- **Attention-maintained aggression** — Aggression that reliably produces adult attention; the treatment is differential reinforcement of the appropriate behaviour and the planned ignoring of the aggression.
- **Differential reinforcement of compliance (DRC)** — The reinforcement of compliance with a demand together with the extinction of the escalation; the core treatment for escape-maintained aggression.
- **Planned ignoring** — The deliberate and complete non-response to a behaviour, with no eye contact, speech, or signal, used to extinguish attention-maintained behaviour.
- **The escalation sequence** — The detailed record of the adult behaviour and the young person's behaviour during an escalation; usually the most informative single component of the analysis of aggression.
- **Establishing conditions** — The historical circumstances in which the behaviour was first performed and acquired its function.
- **Setting demands** — The automatic, attention, escape, and combined demands describing the circumstances under which the behaviour occurs.
- **The behavioural alternative** — A behaviour that is functionally equivalent to the target behaviour and is more efficient, more acceptable, and less dangerous.
- **Extinction burst** — A temporary increase in the frequency or intensity of behaviour at the start of extinction, which is expected and should be predicted to the young person and the team.
- **Restrictive intervention** — Physical restraint, seclusion, or the chemical equivalent; a last-resort intervention of shortest possible duration.
- **Last-resort intervention** — An intervention used only when the young person poses an imminent danger and less restrictive measures have been tried and failed.
- **Manifestation determination** — The procedural requirement, under disability legislation, that a behaviour resulting in a change of placement be assessed against the possibility that it is a manifestation of the young person's disability.
- **Functional behavioural assessment (FBA)** — The assessment required in many jurisdictions before a change of placement for a student with a disability.
- **Medical review** — The systematic review of medication, pain, sleep, seizures, nutrition, and the sensory environment, conducted before the behavioural analysis of a dangerous behaviour.
- **The mood-disorder presentation of aggression** — Irritability as the characteristic presentation of a depressive episode in adolescence, frequently misreferred as aggression.

**Key Terms at a Glance (continued)**

- **Lesch–Nyhan syndrome** — A rare genetic disorder associated with a characteristic pattern of severe self-injury and with a neurochemical profile that is substantially responsive to pharmacological management.
- **Corneal self-injury in Smith–Magenis syndrome** — A characteristic and severe self-injurious behaviour associated with a specific genetic syndrome and with a distinctive sleep disturbance.
- **Dignity protection** — The clinical practice of designing safety interventions so that they are not experienced by the young person as punishment.
- **Restoration goal** — The explicit target of returning the young person to the least restrictive environment in which the behaviour can be managed.

## 12. Chapter Summary

This chapter treated two behavioural presentations that are severe enough to require a different set of clinical conventions from the rest of the book, and it stated the safety-first framework at the outset: the safety of the young person comes first and is not contingent on the completeness of the assessment; the least restrictive effective procedure governs the intervention; the treatment of the behaviour is not the treatment of the condition; and the intervention must be accompanied by a plan for the young person's dignity.

The history explained why the field arrived where it has: the institutional tradition treated unexplained behaviour harshly, and the decisive development was the experimental analysis of self-injury, whose central finding — that the behaviour is overwhelmingly maintained by automatic reinforcement — changed practice fundamentally, because containment removes the behaviour without removing the contingency that produces it. The parallel work on aggression established that much of it is escape-maintained, which is the direct opposite of the assumption embedded in most schools' responses.

The safety hierarchy was set out at four levels, and the safety plans for self-injury and for aggression were described in their five components each, with the escalation procedure and the return condition identified as the most important and the most frequently improvised elements. The position on restrictive interventions was stated plainly: last resort, shortest duration, with oversight, and associated with higher rates of injury and worse outcomes, which is an argument for the seriousness of their use and for the institutional responsibility to design them out of the environment.

The clinical presentations were described with their differential diagnoses, and two specific points were emphasised: the genetic syndromes in which pharmacological management is a substantial part of the treatment, and the mood-disorder presentation of aggression in adolescence, which is frequently misreferred to a behaviour service. The assessment was described as a comprehensive exercise, with the risk assessment identified as a separate document with a separate structure.

The functional analyses of both behaviours were described in detail, with the conditions, the interpretation, and the establishing conditions, and the treatment of the escape-maintained case of aggression was set out in the detail in which it must be implemented, including the predicted extinction burst and the requirement for the adults' response to the escalation to be specified, trained, and consistent.

The case of Marcus demonstrated the sequence in operation and, in doing so, demonstrated the limits of the method. The experimental analysis found the automatic function and the treatment addressed it, and the young person's own account, offered in the eighth week, named the escape function that the plan had not addressed. Both were correct, and the argument of the case is that the young person's own account is data, is gathered as early as possible, and is a supplement to rather than an alternative to the experimental analysis.

The evidence is methodologically mature for the functional analysis and for function-based treatment, and the evidence on restrictive interventions is consistently negative. The limitations were stated: the small and highly selected samples, the behavioural rather than experiential outcome measures, the single-case designs, the under-researched long-term outcomes, and the cultural narrowness of the literature.

The ethical requirements were set out in full — least restrictive procedure with documented alternatives, proportional and documented restrictive interventions, dignity protection with three specific practices, the right to be heard and to complain, the right to the least restrictive environment with a restoration goal, family inclusion with practical support, team coordination, and the refusal to instrumentalise the young person. The cultural analysis addressed the culturally and legally specific definition of danger, the culturally framed meaning of the behaviour, the variable role of the family, and the severe social stigma that follows the young person long after the behaviour has stopped.

## 13. Review and Discussion Questions

**Review and Discussion Questions**

1. State the four elements of the safety-first framework and explain why the order is not negotiable.
2. Describe the four levels of the safety hierarchy and the work that belongs at each.
3. State the five components of a safety plan for self-injury.
4. State the five components of a safety plan for aggression, and identify the one that differs in kind.
5. Explain the role of the early indicators and why they are the most valuable output of the descriptive assessment.
6. State the four clauses of the professional position on restrictive interventions, and summarise the evidence on their use.
7. Describe the differential diagnosis of self-injurious behaviour, and state the clinical consequence of each major category.
8. Describe the differential diagnosis of aggression, and explain why the mood-disorder presentation is frequently missed.
9. State the six components of the assessment of dangerous behaviour, and explain why the risk assessment is a separate document.
10. State the four stages of the functional analysis of self-injury and explain the order.
11. Describe the six experimental conditions and state what each is designed to detect.
12. Explain the difference between the function, the setting demands, and the establishing conditions.
13. Explain the three modifications required in the functional analysis of aggression.
14. Describe the six steps of the treatment of the escape-maintained case of aggression.
15. Explain the role of the density of the reinforcement schedule in the early phase of differential reinforcement of compliance.
16. Explain why the plan for the aftermath of an aggressive episode is a clinical task and not a courtesy.
17. Describe the case of Marcus and state the two arguments it makes about the method.
18. Summarise the status of the evidence for the functional analysis of self-injury and for function-based treatment.
19. Summarise the evidence on restrictive interventions and explain its clinical and ethical implications.
20. State the five limitations of the evidence base.
21. State the five strengths and the five limitations of the functional approach to dangerous behaviour.

**Review and Discussion Questions (continued)**

22. Explain the four cultural considerations that bear on this work.
23. State the ten ethical requirements for work with dangerous behaviour, and explain the significance of the documentation requirement.
24. Explain the three specific practices that protect the young person's dignity.
25. Explain the significance of the right to the least restrictive environment and of the restoration goal.

## 14. Practice Activities

**Practice and Application**

### Activity 29.1 — The Safety Plan (90 minutes, individual)

Write a complete safety plan for a fictional young person with a behaviour that is dangerous to themselves. Specify the functional prediction, the early indicators, the response to the early indicators, the response to the behaviour, the provision of the alternative, and the response after an episode. Then write the specific sentence that an adult will say to the young person at each of the three points. The sentences are the hard part, and the exercise produces a plan that is genuinely usable rather than a document that satisfies a template.

### Activity 29.2 — The ABC of a Dangerous Behaviour (75 minutes, field-based)

With supervision, record the antecedents, the behaviour, and the consequences of a dangerous behaviour in a placement, using the detailed record rather than the summary one. Record in particular what the adult did immediately after the escalation, because the escalation sequence is usually the most informative component of the whole assessment. Then write the two competing functional hypotheses and the observation that would distinguish them. Do not intervene in the escalation, and do not record information that identifies the young person to anyone who does not need it.

### Activity 29.3 — Restorative versus Extinction (60 minutes, small group)

In groups of three, take a behaviour maintained by escape and design two plans: one that uses differential reinforcement of compliance with extinction of the escalation, and one that uses a restorative approach in which the young person repairs the consequence of the escalation. Identify what each plan predicts will happen in the first two weeks, and identify what each plan requires of the adults. Then explain why a plan that mixes the two approaches is usually worse than either. The discussion of the adults' requirements is where the exercise earns its value.

### Activity 29.4 — The Dignity Audit (45 minutes, individual)

Take a safety plan for a young person, real or fictional, and audit it from the young person's point of view. For each element, write what the young person will think and feel when it happens. Then revise the plan so that the young person's experience of it is defensible. The revisions are usually small — the timing of a warning, the choice of a location, the wording of a sentence, the presence of an audience — and the sum of them is the difference between a plan the young person co-operates with and one they will not.

## 15. Annotated Reading Pathways

**For the method.** Read Iwata and colleagues (1982) and then the 1994 book, and read the chapter on the functional analysis of self-injury in any current applied behaviour analysis textbook. The 1982 paper is short and is still the best introduction to the logic of the experimental analysis of dangerous behaviour.

**For the treatment.** Read Aman and colleagues (2000) and the current treatment reviews, and read the population-specific chapters on autism spectrum disorder and on the genetic syndromes. The pharmacological section is not optional in those populations.

**For the safety and the law.** Read the local regulations on seclusion and restraint, and read the professional position statements. Read them before working in the area, not after an incident.

**For the evidence.** Read the reviews of function-based treatment and the studies of restrictive interventions, which are consistently negative and which are the most important empirical basis for the ethical position in this chapter.

**For the ethical and cultural analysis.** Read the disability rights literature on the treatment of people who are dangerous and on the rights of people with intellectual disabilities, and read the literature on the social exclusion that follows a history of violent behaviour. The combination is the preparation for the part of the work that happens after the behaviour has stopped.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Functional Analysis of Self-Injurious and Aggressive Behaviour** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is safety-oriented assessment and intervention with behaviour that is harmful or dangerous. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is functional analysis, learning history, contingencies, mastery, and measurable behaviour change. The mechanism to keep in view is how antecedents, consequences, skills, avoidance, and environmental design select and maintain behaviour. The characteristic professional risk is using control without assent, reinforcing compliance rather than wellbeing, or ignoring the meaning and function of behaviour. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in classrooms, homes, clinics, and other real environments where behaviour occurs, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable,

and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Sofia is fifteen and is seen in a family support service for sleep disruption, irritability, and falling participation. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Sofia's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Sofia explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through

repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on functional analysis, learning history, contingencies, mastery, and measurable behaviour change. The first intervention is deliberately modest. Sofia chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Sofia has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Sofia can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.

- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Functional Analysis of Self-Injurious and Aggressive Behaviour

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Functional Analysis of Self-Injurious and Aggressive Behaviour** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Functional Analysis of Self-Injurious and Aggressive Behaviour** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Functional Analysis of Self-Injurious and Aggressive Behaviour**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

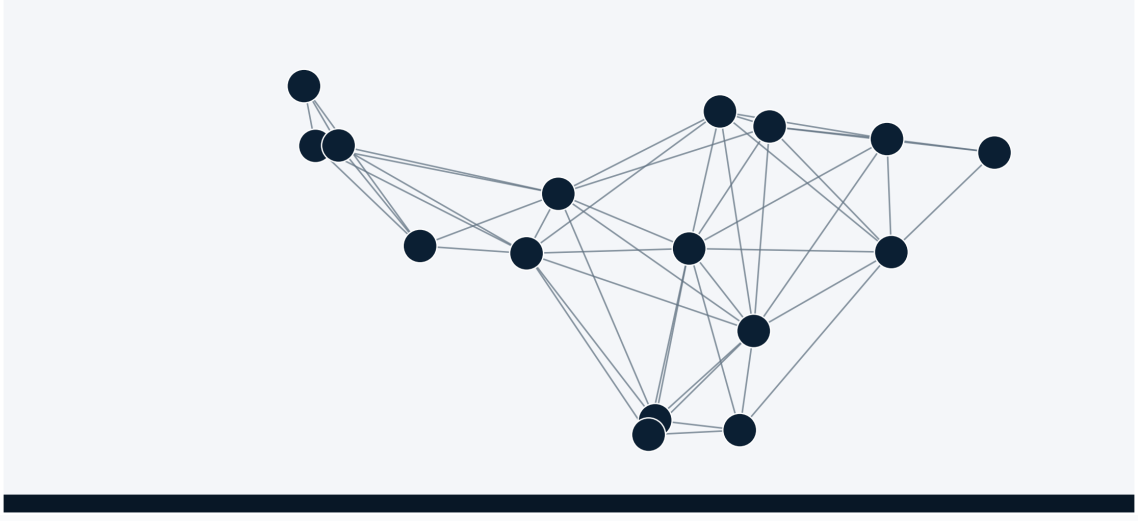
**Written consolidation.** In 250 words, explain Functional Analysis of Self-Injurious and Aggressive Behaviour to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

PART V

# Systemic, Family, and Relational Theories

Theories that locate the individual inside a network of relationships and meanings: the systemic turn, the family as the unit of treatment, and the narrative and solution-oriented traditions.

## CHAPTERS IN THIS PART



30 Family Systems Theory: Bowen and the Generational Project
31 Structural Family Therapy
32 Strategic Family Therapy and Communication Theory
33 Family Therapy with Parents and Adolescents
34 Attachment Theory and Attachment-Based Therapy
35 Solution-Focused Brief Therapy and Strength-Based Practice
36 Narrative Therapy and the Re-Authoring of Lives

CHAPTER 30

# Family Systems Theory: Bowen and the Generational Project

Differentiation, triangles, nuclear family emotional process, and the genogram as a clinical tool.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the development of the family systems tradition, from the early family therapy movement to Bowen's work and its descendants.
- State the eight core concepts of Bowen's family systems theory and explain the clinical significance of each.
- Explain the concept of differentiation of self, and distinguish it from individuation, autonomy, and emotional detachment.
- Describe the formation and function of triangles, and explain why almost all clinical material with a young person is triadic.
- Describe the nuclear family emotional process, including the concept of the emotional cutoff and the generation of the family projection process.
- Construct a genogram, and explain its uses in assessment and in intervention.
- Apply the Bowen framework to a case involving an adolescent and a family, and evaluate the limits of the framework.
- Critically evaluate the cultural and ethical dimensions of generational family systems work.

## Chapter Overview

Bowen's family systems theory is unusual in the counselling field in two respects that a student should appreciate before reading the theory.

The first is that it is a **theory of the whole of a person's life in a small number of concentric circles**. Bowen did not treat the family as one system among many, nor as a context for an individual problem. He treated the family as the fundamental unit of emotional life, and he described the person's functioning as a series of nested systems — the two-person dyads, the triangles, the family subsystems, the family, the extended family, and the wider community and culture — each of which is governed by the same processes at a different scale. A young person's symptom is therefore not a disorder located in the individual but a symptom of a disturbance in the process of the family, and it can be read at every level simultaneously.

The second is that it is a **theory with a clinical method attached to the assessment**. Bowen developed the genogram — the family diagram — as a clinical instrument, and his use of it to trace the patterns of relationship across three or four generations is the most distinctive contribution of the tradition to the practice of counselling. The genogram does something that no other clinical tool does: it makes the intergenerational dimension of a young person's difficulty visible, and it makes it visible in a form that a family can look at together.

The theory's weaknesses are as well known as its strengths, and they should be understood before the theory is applied. Bowen did not conduct controlled outcome research, and the evidence base for the theory as a whole is weak, with the evidence concentrated on specific applications such as family-based treatment of eating disorders and of substance use, where the family component has a demonstrable effect. The theory's assumption that the family is the fundamental unit of emotional life does not hold in the same way for every young person, and the account of the family as a system of emotional processes has been criticised for a tendency to locate the problem in the family when the problem has been located in the wider social

structure.

This chapter presents the theory in its technical form, the genogram as a clinical method, and the adaptations that the work with young people requires.

# 1. Historical Context

## 1.1 The origins of family therapy

Family therapy emerged in the United States in the 1950s, and it emerged because of a clinical problem that the individual model could not solve: a substantial number of patients improved in individual therapy and then relapsed as soon as they returned to their families. The observation was so consistent that it forced a reorientation, and the reorientation took the form of a simple and radical proposition — that the family, not the individual, is the unit of treatment, and that the symptom is a function of the family's structure and its patterns of interaction.

The early work was conducted in two settings that were quite unlike any contemporary mental health service. The first was the **child guidance clinics**, where the child was understood to be the identified patient and the family was understood to be the context; the second was the **institutions**, where the deinstitutionalisation movement exposed the extent to which chronic disturbance was maintained by the institutional structure itself.

The field's founding figures were diverse in background and in method, and the diversity is instructive. **Murray Bowen**, a psychiatrist and psychoanalyst, developed the family systems theory and the genogram. **Virginia Satir**, a social worker, developed a humanistic and skills-oriented family therapy. **Salvador Minuchin**, a psychiatrist, developed the structural model. **Jay Haley**, a communications specialist, developed the strategic and communication approaches. **Carl Whitaker**, an experiential therapist, developed a distinctive and influential model of the family as a developmental context.

The division that emerged between the "structural" and "strategic" camps, and later between Bowen and the others, is partly a matter of theory and partly a matter of professional temperament, and a student should know that the family therapy field has never been a unified discipline.

## 1.2 Bowen and the generation of the idea

Bowen's training was in psychoanalysis, and he was in the unusual position of being able to see the limits of the individual model from within it. His central clinical observation was that his analysands' families reproduced their symptoms in the session: a patient who was withdrawn in the consulting room had a family that was warm and intrusive in the family room, and a patient who was anxiously enmeshed had a family that was cool and distant at home.

The implication was that the anxiety was not located in the individual but was a *product of the relationships*, and that the individual patient's symptom was a consequence of the position he occupied in the family system. This is the shift from intrapsychic to interpersonal causation, and it is the shift that the entire family systems tradition rests on.

Bowen's theoretical contribution was to make the interpersonal shift *quantitative* and *generational*. The family was not a single system; it was a nested set of systems governed by the same processes at different scales, and the processes had a lineage that ran through the generations.

### 1.3 The development of the tradition

Bowen's own practice was unusual. He worked with families of varying composition, he used the genogram as a routine part of assessment, he was interested in the transmission of emotional processes across generations, and he formulated in a language that was intended to be shared with the family rather than concealed from it. He was also, characteristically, cautious about the ambition of the systemic work: he described his approach as a way of *thinking about* a family rather than a technique for *treating* one.

The descendants of the tradition are numerous. **Murray Bowen, Jr.** and the group at the Family Institute in Washington developed Bowenian family therapy and the clinical training that carries his work forward. **Carl Whitaker's** experiential family therapy, developed in parallel, is distinctive in its attention to the emotional experience of the family members and in its refusal to take the identified patient's account at face value. **Murray Bowen's** articulation also informed the **structural** and **strategic** schools, which are the subjects of Chapters 31 and 32.

### 1.4 The reception

Two distinct lines of reception are important for a student.

**The clinical reception.** Bowenian family therapy is widely used in academic training and in a minority of clinical settings, and it is influential well beyond its direct practice, because the genogram is now a standard tool in assessment in family therapy, in safeguarding, in school counselling, and in adoption and fostering practice.

**The critical reception.** The theory has been criticised on several grounds, and each is worth stating because each identifies a real limitation.

**It is empirically thin.** Bowen did not conduct controlled outcome research, and the research literature on Bowenian family therapy is small. Where family-based approaches have been shown to work, the demonstrations are usually of components — family-based treatment of adolescent eating disorders, family therapy for substance use, behavioural family therapy for conduct problems — rather than of Bowen's theory as a whole.

**It risks a circularity.** If a young person's difficulty is understood as a product of the family, and the family's patterns are understood as the products of earlier generations, and the earlier generations are understood in the same terms, then the young person can end up as the tip of a lineage rather than as a person, and the clinical work can end up directed at the ancestors.

**It under-accounts for the structural.** The theory treats the family as a system of emotional processes, and it can under-specify the material and political realities within which the family lives: poverty, racism, migration, unemployment, housing, and the effects of state decisions on the family's capacity to function. A formulation that attributes a family's difficulties to its internal emotional process risks locating the problem in the family when the problem has been located in the conditions.

**It assumes a family.** The theory presupposes a coherent and continuing family system. For a young person in care, for a young person separated from parents, for a young person in a family that has been dissolved by migration, conflict, or violence, the presupposition does not hold, and the practitioner must adapt the theory substantially or work with a different one.

## 2. The Systems Perspective

## 2.1 The eight core concepts

Bowen's family systems theory is conventionally described in terms of eight core concepts, and a student should be able to state all eight and give an example of each in a family with a young person.

1. **Two-person systems**, in which the relationship between two individuals is the primary unit of emotional life.
2. **Differentiation of self**, the degree to which a person can maintain a clear sense of self within an emotional relationship.
3. **Triangles**, the three-person systems that form when the tension between two people is relieved by the involvement of a third.
4. **Nuclear family emotional process**, the transfer of emotional process from one generation to the next, transmitted through the parental subsystem.
5. **Emotional cutoff**, the process by which a family member distances from the family in order to avoid anxiety, and the transmission of that cutoff across generations.
6. **The multigenerational transmission process**, the description of how emotional processes are transmitted across generations.
7. **The family projection process**, the mechanism by which the parental subsystem transmits its own emotional process to a child.
8. **Sibling position**, the way in which a child's position in the birth order shapes the family's emotional process.

Two further concepts, the **sociocultural emotional process** and the **family emotional system**, complete the framework. The sociocultural process describes the way in which the emotional processes of a family are shaped by the wider culture, and it is the concept through which the theory can be brought to bear on the structural questions that the theory otherwise under-specifies.

## 2.2 The nested systems

The defining feature of the framework is that it is **scale-invariant**: the same processes operate at every level of the system.

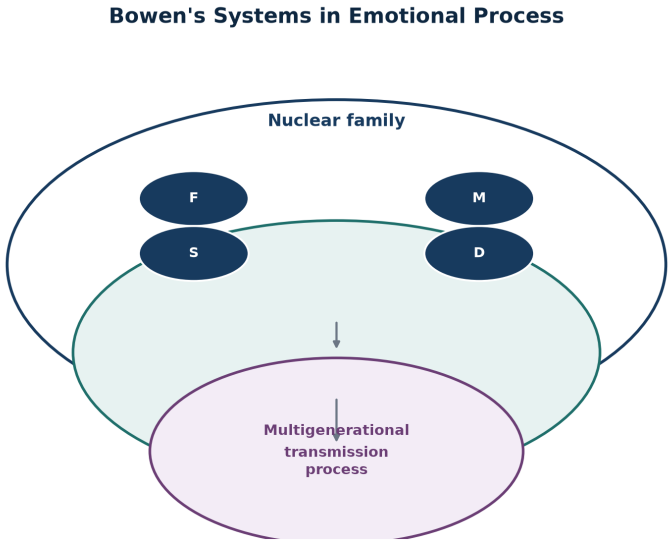


**Figure 30.17** Bowen's nested systems, showing the concentric levels from the two-person dyad through the triangle and the family subsystems to the wider family, the community, and the culture.

At the level of the **two-person system**, the fundamental emotional reality of the human being is the capacity to relate to another. Bowen was explicit that this is a level of *emotional* relationship and not of *rational* contract, and the distinction matters: a person can be entirely clear about the terms of a relationship and entirely unable to maintain a defined self within it.

At the level of the **triangle**, tension between two people is relieved by the involvement of a third, and the two sides of the triangle are in a state of tension with each other while the third is in a state of tension with both. Almost all emotional conflict in families involves triangles, and the practitioner who cannot identify the triangle will not understand the case.

At the level of the **family**, the sub-systems — the parental, the sibling, and the individual — are pulled towards a lower level of differentiation under stress, and the symptom is the mechanism by which the tension is held in the system.

At the level of the **extended family and the community**, the processes continue, and the community and the culture become the wider contexts in which the family negotiates.

## 2.3 The governing laws

The framework is described by two governing laws, and they are the most quoted and least understood part of it.

**Law one: the preservation of self.** Bowen drew this from William James and from the philosophical literature, and it states that the organism is a whole and that the function of the whole is to preserve the whole — that is, the individual. The "self" in the law is a functional term: it refers to the capacity of the organism to maintain its integrity and to function as a whole.

**Law two: the preservation of the family** — or, in its common formulation, the emotional system of the family is more important than any individual member of it.

The two laws are in tension, and the tension is the source of the clinical problems the theory describes. Under stress, the family system pulls the individual towards the family (law two), and the individual resists (law one), and the visible result is a symptom in one of the members.

A student should be able to explain the laws and their tension, and should resist the interpretation — which is widespread in the popular literature — that the theory counsels self-sacrifice or family loyalty. It does not. It says that the pull towards the family and the push towards the self must be balanced in a way that permits both, and that the balance is called differentiation.

# 3. Differentiation of Self

## 3.1 The concept

**Differentiation of self** is the degree to which a person can maintain a sense of self within an emotional relationship — the capacity to think, to act, and to feel in a way that is determined by one's own convictions rather than by the emotional pressure of the relationship, while remaining fully engaged in the relationship.

Three elements are involved: the **thoughts**, which are not contaminated by the emotional pressure of the situation; the **feelings**, which are not overwhelmed by the pressure of the situation; and the **actions**, which are not determined by the pressure of the situation. The degree of differentiation is the degree to which these three are congruent with each other and with the person's own position.

The key phrase is *within an emotional relationship*. Differentiation is not the same as independence, and a person who leaves the family, or who refuses to feel anything, or who maintains a position at the cost of every relationship, is not differentiated. And it is not the same as emotional detachment, which is the avoidance of emotional involvement in order to protect the self.

## 3.2 The two extremes

The two poles of the continuum describe the two characteristic family positions.

**The undifferentiated position** is characterised by the flooding of thought, feeling, and action by the emotional process of the relationship. The person cannot think clearly in the presence of the conflict, cannot modulate the feeling, and acts impulsively or rigidly. In the family this position is often occupied by the person who is the most involved in the family's emotional process.

**The cut-off position** is characterised by the reduction of emotional involvement in order to preserve the self. The person thinks and acts clearly, but at the cost of feeling, and the feeling is often displaced into physical symptoms, into a narrow pursuit, or into the body. The cut-off is a *process* and not a position, and it is a process in motion, which is why the families of cut-off young people often describe an abrupt disconnection — a departure, a marriage, a collapse in contact.

Between the two poles lies the differentiated position, in which a person can be close and can be autonomous, can feel deeply and can think clearly, and can disagree and can remain in the relationship.

## 3.3 The clinical significance

Differentiation is the central clinical concept, and it operates at two levels: the intrapersonal and the interpersonal.

**Intrapersonal differentiation** is the difference between the person's various states. A differentiated person can recognise that the anxiety she feels about her mother's phone call is not the same thing as the anger she feels about the last thing her mother actually said, and can distinguish between the fact and the interpretation, and can act on the fact.

**Interpersonal differentiation** is the difference between the people in the relationship. A differentiated parent can hold two different views — "my daughter is suffering" and "my daughter is also refusing to see me" — without collapsing the one into the other, and can express both to the daughter at the same time.

The clinical targets follow directly. A family with a symptomatic young person typically contains at least one undifferentiated member, whose flooding is transmitted to the others, and typically contains at least one cut-off member, whose disconnection leaves the family to manage its own anxiety. The work is to increase the differentiation of the family, and the symptom is what will reduce as a by-product.

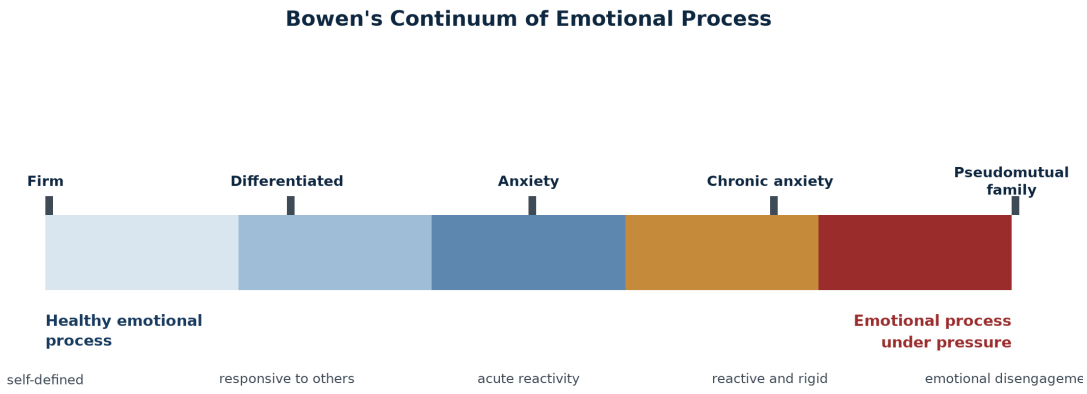

**Figure 30.18** The two poles of differentiation, showing the movement of thought, feeling, and action from the undifferentiated position through the differentiated position to the cut-off position.

## 3.4 Emotional process in the body

Bowen's clinical observation that the emotional process is transmitted through the body is one of the most immediately useful and least theoretical parts of the tradition, and it has a direct place in a book for practitioners who work with young people.

The observation is that family members' bodies synchronise in the presence of tension. Posture, breathing, heart rate, and muscle tension change together, and the change is observable in a session within minutes, and the practitioner can use it as a data source. Bowen wrote about the "body copy" of the family emotional process, and the observation is the ancestor of the somatic and interpersonal neurobiological work in Part VI.

For a practitioner, three practical consequences follow. The young person's somatic symptoms may be a direct expression of the family process, and the treatment of a recurrent unexplained physical complaint should include a look at the family system. The practitioner's own body is a diagnostic instrument, and the practitioner can learn to notice their own somatic response to a family member. And a family that is being asked to talk about its emotional process should be prepared for the somatic experience of doing so, and the practitioner should expect an increase in somatic presentation in the early sessions.

# 4. Triangles

## 4.1 The formation of a triangle

A **triangle** forms when the tension between two people is relieved by the involvement of a third, and it has two sides. In a **comfortable triangle**, the two sides are in tension with each other and the third person is in tension with both. In a **conflictful triangle**, the two sides are in tension with each other and the third person is in tension with one side and aligned with the other.

The transfer of tension into a triangle is a universal human process and it happens in the consulting room as well as in the home. A young person who is anxious about a parent's marriage will frequently become the focus of the parents' conflict, and the parental conflict will frequently stop when the young person becomes symptomatic, because the symptom has provided a third position that both parents can occupy.

## 4.2 The clinical importance of triangles

**Almost all emotional conflict is triadic.** A practitioner who works with the identified patient alone is working with one vertex of a triangle and has no information about the other two. This is a practical argument for including the family, and it is an argument the theory makes without any appeal to family loyalty.

**The symptomatic member is usually the most involved.** In a family with a symptomatic young person, the young person is frequently the most enmeshed, and the parents are frequently the more differentiated, and the pull towards the family is what produces the symptom.

**Every triangle must be tracked.** The practitioner working with a family learns to ask, of every conflict between two people, "who is the third?" — and the answer, when it is found, explains the conflict that would otherwise be puzzling.

**The symptom stabilises the triangle.** This is the crucial clinical point, and it explains the family's resistance to change. The symptom is what holds the tension in the family at a manageable level, and removing it without substituting another structure releases the tension, and the released tension is experienced by the family as a catastrophe. A practitioner who removes a symptom quickly and does not replace the triangle structure has produced a worse outcome, and the family will describe the change as an escalation.

The clinical implication is that a plan for a young person whose symptom is doing structural work must include a plan for the family.

## 4.3 The "just" relationship

A specific and useful clinical distinction is between the **intense** and the **"just" relationship**. In the just relationship, the people involved maintain contact and mutual support while keeping the emotional intensity low. A young person who is in a just relationship with a parent continues to see the parent, continues to talk to the parent, and does so without the fusion and the conflict that characterise the intense relationship.

The just relationship is the target of most systemic work with a young person: not the resolution of the conflict but the reduction of the intensity, and the establishment of a workable low-intensity contact.

# 5. The Nuclear Family Emotional Process

## 5.1 The transmission

**Nuclear family emotional process** is the description of the way in which the emotional process of the parental subsystem is transmitted to the children, and it is the mechanism by which the intergenerational transmission occurs.

The transmission is not of content but of **process**. What is transmitted is the *way of handling emotional tension* — the level of differentiation, the capacity to sustain anxiety, the pattern of triangulation, the response to conflict. A parent who cannot tolerate anxiety and who resolves it by triangulation transmits the capacity to tolerate anxiety to the children, and the children develop the same intolerance, and the intolerance is expressed in the next generation as a symptom.

## 5.2 Emotional cutoff

**Emotional cutoff** is the process by which a family member reduces emotional involvement with the family in order to reduce anxiety, and it is the most common response to a family system that is too intense for the individual to bear.

It is worth distinguishing three forms, because they have different clinical consequences. The **healthy cutoff** is a psychological separation that permits the individual to function in a family that cannot be changed; the young person who goes to boarding school and maintains a warm relationship with the parents has made a healthy cutoff. The **internal cutoff** occurs within the family, in which the person remains in contact but ceases to be emotionally available; this is the young person who is physically present and psychologically elsewhere. The **external cutoff** is a physical or social severance; this is the young person who is removed from the family or who removes themself.

## 5.3 The family projection process

The **family projection process** is the mechanism by which the parental subsystem transmits its own emotional process to a child, and it is the specific mechanism that makes the transmission intelligible.

The process has two linked components.

**The projection** is the transmission of the parents' own unresolved emotional issues, attitudes, and emotional needs to the child. The parent projects onto the child a part of their own emotional world, and the child is shaped by the projection.

**The introjection** is the child's absorption of the projected material, which becomes part of the child's own emotional structure. A child who has been the object of a parent's projection of their own anxiety and their own unmet needs will internalise that anxiety and those needs, and will grow up with the sense of being responsible for the regulation of someone else's emotional state.

The clinical significance is the explanation it provides for the young person who is over-responsible, who is the family's emotional caretaker, who cannot let anyone else worry, and who finds it impossible to be in need. This is one of the most recognisable presentations in the family literature, and it is very often mistaken for a young person's character trait.

## 5.4 Sibling position

**Sibling position** — the order, the age gaps, the sex composition, and the number of children in the family — shapes the family emotional process. Bowen described the "sibling position" in terms of the child's place

in the birth order and the emotional characteristics associated with the position, and the descriptions are provocative and should be treated as hypotheses rather than as findings.

The useful clinical proposition is the one about the family projections: a family with two children tends to focus its projection on one of them, and the choice is often determined by the compatibility of the child's temperament with the parents' unresolved issues, and the child who is the focus of the projection is frequently the one who presents with the symptom, and frequently the one who is described as the "good" one.

The other useful proposition concerns the **family projection of a sibling position into the parental system**: a child who occupies the position of a parent's own sibling, and who resembles that parent, will receive a particular intensity of projection.

# 6. The Genogram

## 6.1 The instrument

The **genogram** is a family diagram, and it is Bowen's most widely used and most widely borrowed clinical contribution. It extends the pedigree — the standard family tree that traces biological descent — into a map of the *relationships* in the family across three or more generations.

The genogram records: the biological and the marital structure of the family; the names and the ages of the members; and, at a series of concentric levels, the social, psychological, medical, and emotional information about each member.

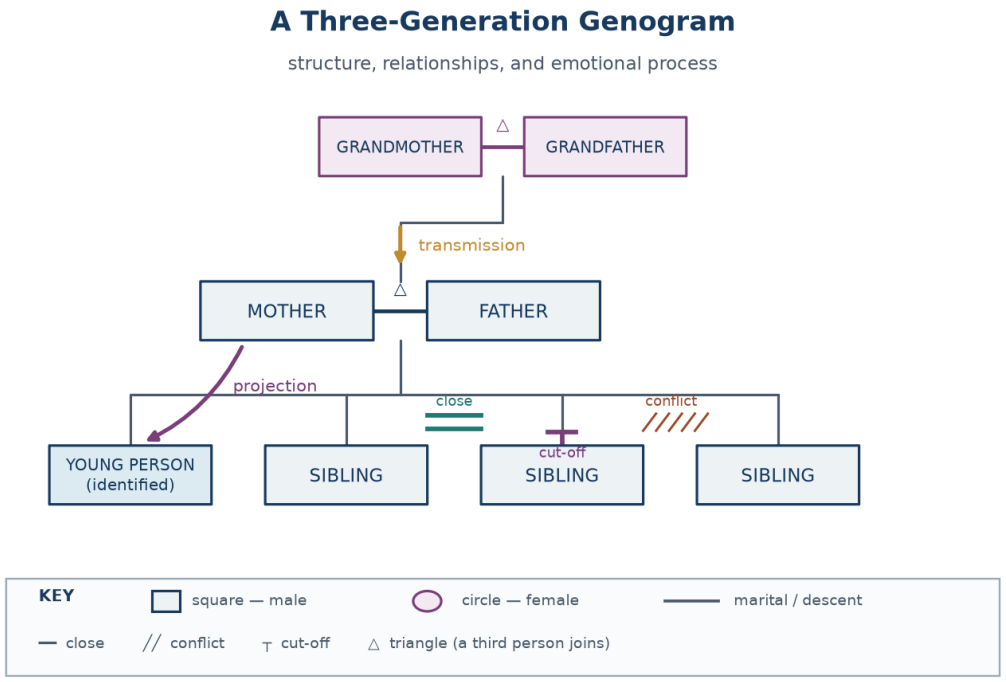

**Figure 30.19** A three-generation genogram showing the standard symbols for marital and descent lines, close and conflicted relationships, cut-off, and the triangle.

The levels are the key to the instrument. The **social** level records education, occupation, ethnicity, migration, and socio-economic status. The **psychological** level records the significant emotional events — the losses, the abuse, the mental illness, the substance use, the suicide attempts, the relationship ruptures — and the quality of the relationships between the members. The **medical** level records the illnesses, the genetic conditions, and the causes of death.

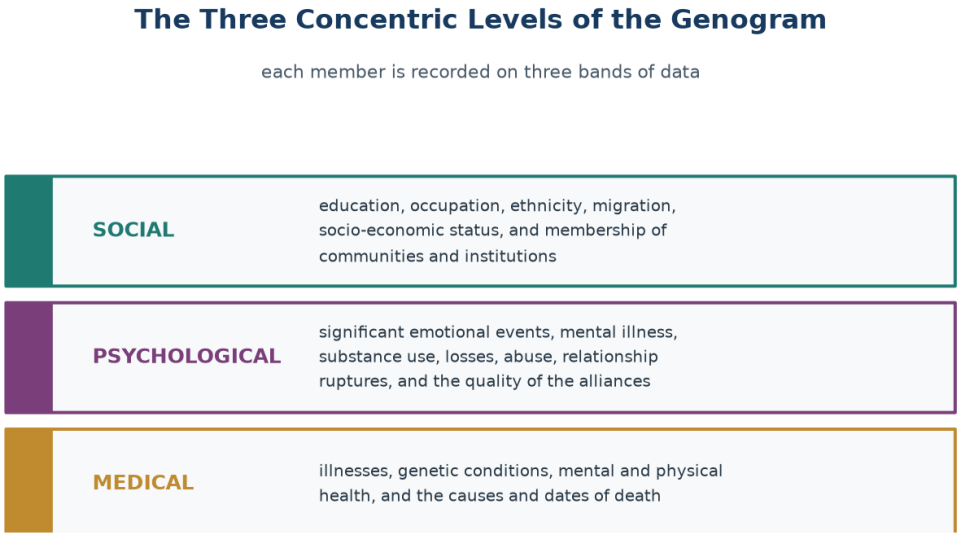

**Figure 30.20** The three concentric levels of the genogram, showing the social, psychological, and medical data recorded for each family member.

## 6.2 The procedure

The construction of a genogram is a clinical conversation, and it should be done with the family and not about them.

**The first session** establishes the structure: the marriages, the separations, the divorces, the children, the adoptions, the step-relations, the losses, the migration, and the family contacts that have been lost. The practitioner draws the genogram as the family speaks, because the drawing is itself a communication.

**The second session** adds the emotional level: the relationships, the alliances, the conflicts, the estrangements, the closeness. The symbols for these are the ones the family recognises immediately, and the genogram becomes a shared object that the family can see.

**The third session** adds the emotional process: the triangles, the cutoffs, the projections, the areas of intensity and of low intensity.

**The fourth session** addresses the family projection process, and the fifth the multigenerational transmission process.

## 6.3 The uses

The genogram is used for three distinct purposes, and it is worth separating them because they have different status.

**As an assessment instrument**, the genogram is of value in its own right. It is the most efficient way to discover the presence of a pattern that has been operating for three generations, and the discovery of such a pattern often reorganises the family's understanding of its own difficulty. A family that has always understood its difficulty as the fault of one member frequently re-describes it, after the genogram, as a long pattern.

**As a therapeutic instrument**, the genogram is used directly in the work. Bowen regarded the genogram as a way of placing the family in the context of its history, so that the current problem is seen as a legacy rather than as a personal failing, and the process of drawing it — with the family — is itself a form of intervention.

**As a supervision and consultation tool**, the genogram is used to make a case comprehensible to a team, and it is a far more efficient communication format than a narrative formulation.

### 6.4 The limits

Three limits should be named.

**It is a retrospective construction, and memory is unreliable.** The genogram is a family's account of its own history, and families' accounts are shaped by the current relationships. A grandmother's role in the transmission of the pattern may be remembered very differently by the grandmother and by the mother, and the disagreement is itself clinically interesting but it does not resolve the question.

**It can be a burden.** A young person who is shown a genogram that documents three generations of illness, loss, and conflict has been given a substantial amount to carry, and a young person who is handed the family pattern and told that it explains them may experience a loss of agency. The genogram should be used with the young person and not presented to them.

**It is not a research instrument.** Its reliability and validity for research purposes are poor, and a practitioner should not present a genogram as evidence.

# 8. Bowenian Work with Children and Adolescents

## 8.1 The fit

Bowenian thinking is unusually well suited to the developmental stage at which most clinical referrals of adolescents occur, and the reasons are worth stating before the clinical material.

**The adolescent's task is differentiation.** The developmental work of adolescence is precisely the work that Bowen's second core concept describes: the maintenance of a self within an emotional relationship, the increasing distance from the family of origin, the construction of a peer world that is not the family, and the eventual establishment of a life that is one's own. A theory whose central concept is the adolescent's central developmental task has an unusual advantage.

**The symptom has structural function.** The adolescent's symptom — the withdrawal, the defiance, the school refusal, the eating, the substance use — is very often doing the work of holding the family's emotional process in a manageable configuration, and a therapeutic approach that works only on the symptom will fail, because the family will re-establish the configuration.

**The triangle is the adolescent's natural habitat.** The adolescent's position between two parents is a developmental fact, and a framework in which the adolescent is understood as the third vertex of a parental triangle is more accurate than one in which the adolescent is understood as an individual with a disorder.

## 8.2 The clinical principles with young people

**Work with the family system, not only with the young person.** This is the theory's most distinctive practical claim, and it is also the one most often resisted. A practitioner who works only with the young person and then attempts to work with the family has usually missed the moment at which the family would have engaged.

**The genogram with the family.** The genogram is the most accessible of the systemic tools, and it works with young people particularly well because it gives the young person a place in a pattern that is larger than their own behaviour. A young person who has been told that their refusal to speak to their father is a character flaw is often relieved to discover that the pattern is a family one.

**Reduce the intensity rather than resolve the conflict.** The target is the *just relationship* — the maintenance of contact without the fusion. Many of the interventions that work with adolescents are simply the establishment of a different pattern of contact, and the establishment of a specific, small, regular contact is often enough to reduce the symptom.

**Watch for the cut-off as a symptom.** A young person who has stopped speaking to a parent is performing a cut-off, and the cut-off may be protecting them from an intolerable fusion, and the question is not how to make them speak but what contact would be tolerable.

**Do not make the young person the agent of change.** A common systemic error is to ask the young person to change in order to relieve the family's tension, which confirms the projection. The young person should not be the one whose behaviour must change so that the parents can feel better.

**Expect the family to resist.** The family's resistance is not an obstacle to the work; it is the material of the work. A family that resists a change has usually found a reason to resist it, and the reason is worth understanding.

### 8.3 The clinical sequence

A workable sequence for an adolescent referral in a Bowenian frame is as follows.

**Session 1: the individual.** An assessment session with the young person, focused on their own account, their own developmental position, and their own view of the family. The purpose is to establish the alliance and to hear the young person's account in their own terms, and the practitioner should resist the temptation to begin the systemic work here.

**Session 2: the genogram.** A session with the young person, or with the young person and one parent, in which the genogram is drawn. The young person is the primary source, and the genogram is drawn with the young person rather than about them.

**Session 3: the family.** The first family session, with the task of drawing the family emotional system, and of establishing the alliances and the conflicts. Bowenian practitioners are characteristically cautious about the intensity of early family work, and the caution is wise with an adolescent, because a first family session that becomes an argument between the parents will confirm the young person's position and drive them out of the process.

**Sessions 4 onward: the work.** The systemic work, most commonly the reduction of the intensity of the central triangle, the establishment of the just relationships, and the differentiation of the parental subsystem, with the work frequently proceeding through the parents rather than with the young person.

### 8.4 Working with a young person who will not come

A common presentation in adolescent services is the young person who will not attend. Bowenian practice has a distinctive and useful answer to this, and it comes from Petter's work on the family member who refuses to participate.

The refusal is itself a systemic communication, and it usually communicates one of a small number of things: that the young person is protecting the family from a conflict the family cannot tolerate; that the young person has been cast as the family's problem-solver and the refusal is a refusal of that role; that the young person is in a position in which the family is negotiating through them and the negotiation is unwinnable; or that the family system will not tolerate the young person's presence.

The response is not to insist on the young person's attendance. It is to work with whoever will come, to treat the refusal as a piece of clinical information about the family, and to establish a direct line of communication with the young person that does not pass through the parents.

## 9. Case Illustration: The Young Woman Who Had Become Her Mother's Confidant

**Presentation.** Ruth is seventeen and lives with her mother, her younger brother, and her mother's partner. She is referred by the school because of what the school calls "anxiety and possible eating problems". Her mother, who attended the first appointment, presents a picture of a young woman who is doing too much, who is anxious, who has stopped eating properly, and who is "very responsible".

**The individual session.** Ruth's own account is different in every particular from her mother's. She describes a household in which she is the person who holds everything together: she does the shopping, she manages her mother's diary, she cares for her brother after school, she mediates between her mother and her mother's partner, and she has been the principal confidant of her mother's difficulties since her father left when Ruth was eleven. She describes her own account of the eating as "not really about food" and, when pressed, as being about the fact that she is the only person in the house who anybody talks to, and that she cannot go anywhere or do anything without someone needing her.

She says one thing that changes the case: "If I stopped doing all of it, I don't know what would happen. I think it would all land on my mum."

**The genogram.** The genogram is drawn in the second session, with Ruth. It shows: a maternal grandmother who had been treated for a "nervous breakdown" after the birth of her second child; a mother who was the eldest of two and who had assumed responsibility for her mother's care from the age of eleven; a father who left when Ruth was eleven; a stepfather who is present in the household but who is not, in Ruth's account, available to her; and a family pattern in which responsibility passes to the eldest daughter. The emotional level of the genogram shows the alliances: Ruth and her mother, and a complete absence of an alliance between Ruth and her mother's partner, whose participation in the family is limited and who is excluded from the confidences.

The pattern is immediately visible, and Ruth sees it. What she says on seeing it is: "Oh. That's my mum and me. That's my mum and her mum, and me."

**The formulation.** Ruth's mother's own history is the same as Ruth's, and Ruth has reproduced it. The family projection process is operating directly: her mother's own emotional needs, and her mother's own unfinished responsibility for her own mother, have been projected onto Ruth, and Ruth has introjected them as her own. The symptoms — the anxiety, the eating, the over-responsibility, the inability to go out — are the consequences of a young woman who is functioning as the emotional and practical parent of a family of three.

The differentiation of the family is very low, and the family is running on the intensity of the Ruth–mother dyad. The triangle is: Ruth, her mother, and her mother's partner, with the third vertex carrying all of the anxiety and all of the blame. There is no other triangle in this family, and the two adults have no relationship to each other that is not routed through the daughter.

**The intervention.** Four elements, and the first is the one that makes the rest possible.

*Element one: the individual work.* Ruth is seen individually throughout, and the work is about the differentiation. The specific interventions are small and concrete. Ruth practises declining a request: the mother asks her to do the shopping and Ruth says, "I can't today, I've got my coursework." The practitioner explores with her what happened when she was a child and her mother was ill, and she recognises, with some difficulty, that the fear of what would happen if she stopped is the inheritance and not a fact.

*Element two: the parental subsystem.* The work with the parents is the essential work, and it is done without Ruth in the room. The first session with the two adults establishes that they have not had a conversation without Ruth present since Ruth was eleven. The second session does something quite specific: it asks the

two adults to talk to each other, directly, for ten minutes, about a topic that is not Ruth, and the practitioner observes what happens. It is not a comfortable exercise, and it is the beginning of the differentiation of the parental subsystem.

*Element three: the genogram with the whole family.* The genogram is presented in a session with all four, and the discussion is about the pattern rather than about Ruth. This is a key technical decision: the family is asked to talk about the pattern in the grandmother and the great-grandmother, and not about Ruth. What the family finds, when they look at the pattern rather than at the symptom, is that there are two women in the family who did this and one who is about to, and that the pattern can stop with Ruth.

*Element four: the practical arrangements.* Ruth's mother and her partner are asked to take on the practical tasks that Ruth is carrying. It is a difficult conversation, and the resistance is predictable: the mother says she does not know how to cook, and the stepfather says he does not know how to manage her. The practitioner treats both statements as material rather than as excuses, and the working arrangement is small and specific — two evenings a week on which the two adults cook, and a specific task that the stepfather takes over.

**The outcome.** At three months, Ruth is eating regularly, is attending school, and is doing less at home. The relationship with her mother's partner has improved, not because of any work directed at it, but because he is now cooking and she is now sometimes at the table. The relationship with her mother is closer and less suffocating, which is what the just relationship looks like in practice.

Ruth's anxiety has not disappeared, and it should not be expected to at seventeen months; the pattern is thirty years deep and the work continues. Her own account at the end is the best available outcome measure: "I can do something on a Tuesday now and nobody falls over."

**The interpretation.** The case illustrates the central claims of the theory. The symptom was not in the young woman. The family projection process was operating across two generations and was visible on a single page of a genogram. The parents' subsystem, which had no channel of its own, was the location of the work. And the outcome measure that mattered — that nobody falls over — is a measure of the family system's capacity to hold itself together, which is what the theory says the work is for.

# 10. Evidence and Research Support

## 10.1 The status of the evidence

Bowen's theory has a thin evidence base, and the student should be able to state this accurately rather than defensively.

**There is no substantial controlled outcome research on Bowenian family therapy as a whole.** Bowen did not conduct it, and the field has not filled the gap.

**The family-based treatment literature is stronger than the theory-specific literature**, and it is in this literature that the actual support for family work with adolescents lies. The findings are:

**Family-based treatment of adolescent eating disorders has good support.** The family-based approaches, in which the parents take a central role in restoring the young person's nutrition and the family addresses the patterns that maintain the disorder, produce better outcomes than the individual approaches, and the effect on the parental attitudes is the mechanism. This is the strongest evidence for the general claim that parental involvement matters.

**Family therapy for adolescent substance use has good support**, particularly the family-based and the multisystemic variants.

**Behavioural family therapy for conduct problems has a strong evidence base**, as described in Chapter 33, and it is a family intervention with a specific behavioural mechanism.

**Multisystemic therapy has a strong evidence base** for serious antisocial behaviour in adolescents, and it is a systemic intervention with the same core premise — that the adolescent's behaviour is maintained in multiple systems and that the systems must be changed — even though its theory is different.

**The genogram has no validated psychometric properties**, and it should not be used as an assessment instrument in any context in which psychometric reliability matters.

### 10.2 What the theory contributes that the evidence cannot capture

The theory's most defensible contribution is a **way of organising the clinical thinking** rather than a treatment with a measurable effect. The genogram and the concepts of the triangle, the cut-off, and the family projection process give a practitioner a language for making sense of patterns that would otherwise be experienced as inexplicable and therefore as personal failings.

This contribution is real and it is undervalued by the evidence, because it is a contribution to the *formulation* rather than to the *outcome*, and because the profession's research methods are better at measuring outcomes than at measuring the quality of a formulation. A student should be able to hold both positions: that the theory is under-researched, and that the framework organises thinking in a way that other frameworks do not.

### 10.3 Limitations of the evidence

**The controlled trials that exist are small**, and the methodological quality is variable.

**The outcomes are proximal** — the resolution of the identified symptom and the improvement of the family functioning — and the distal outcomes, the educational trajectory, the adult relationships, the mental health in the third generation, are not measured.

**The samples are selected**, and the families who complete family therapy are not representative of the families who are referred.

**The allegiance effects are substantial** in the family therapy literature, and the family-based eating disorder trials in particular have attracted considerable methodological scrutiny, including questions about the generalisability of the family approach to a range of severity and a range of family structures.

## 11. Strengths and Limitations of Bowenian Family Systems Theory

### 11.1 Strengths

**It locates the problem.** The theory's central contribution is to move the question from "what is wrong with this young person" to "what is happening in this family", and the move is almost always clarifying.

**It accounts for the resistance.** A family that will not change is described by the theory as a family that has found a reason not to change, and the reason is investigated rather than confronted.

**It de-blames the young person.** The theory is one of the few in this book that actively relieves a young person of the responsibility for the family's state, and the relief is itself therapeutic.

**The genogram is a superb instrument** for assessment, for communication with a team, and for making a pattern visible.

**It is developmentally congruent.** A theory whose central concept is the adolescent's central developmental task fits the stage.

**It is compatible with other modalities.** Bowenian concepts can be combined with behavioural, cognitive, and attachment work without contradiction.

### 11.2 Limitations

**It is empirically thin**, and a student should be honest about this when the approach is presented to a family or a commissioner.

**The circularity risk is real**, and the theory's own answer to it — that the family must be understood in the context of the wider culture — has not been operationalised in a way that reliably prevents the mislocation of structural problems in the family.

**It presupposes a family**, and a substantial proportion of the young people in contemporary services do not have one in the form the theory requires.

**It can absolve the family of accountability.** The most serious misuse of the framework is the deployment of the concepts as a sophisticated-sounding way of explaining a young person's behaviour in terms of the family's dysfunction while changing nothing. A genogram that is drawn and then filed is a way of looking busy.

**It is difficult to learn and difficult to supervise.** The theory is largely transmitted through apprenticeship, and the quality of a Bowenian practitioner varies enormously, and the supervision of this work requires a specific competence.

## 12. Cultural and Ethical Considerations

### 12.1 Culture, family, and the definition of the family

The theory's cultural assumptions are extensive and worth making explicit.

**The definition of the family.** The theory assumes a family with two parents, a nuclear household, and continuity across the generations. In many settings the relevant family is a single parent, a grandparent, an extended kin network, a chosen family, a kinship network that spans a migration, a collective, or a community. The theory's concepts can be applied to these, and a practitioner should learn to apply them to the family the young person actually has.

**The cultural patterning of the family emotional process.** In settings in which the family is a collective rather than a nuclear unit, the individual differentiation that the theory values may be experienced as disloyalty. A young woman who holds a boundary against her mother's wishes in a culture where the mother's authority is absolute is not practising an underdeveloped differentiation; she is risking an exclusion. The theory's concepts must be applied with a working knowledge of the cost.

**The intergenerational respect for elders.** The practice of the genogram surfaces the family's history, and in some families the history includes experiences that the family has not discussed and does not wish to discuss, and the drawing of the genogram can be experienced as an accusation against the grandparents.

**The migration and displacement of families.** For a family separated by migration, conflict, or political violence, the genogram may be a document of loss, and the losses may be the actual clinical material.

## 12.2 The sociopolitical critique

The most serious cultural criticism of the family systems tradition is that it locates the family's difficulties within the family. A young person's school refusal that is produced by a curriculum that does not accommodate her disability, or by a neighbourhood in which it is not safe to walk to school, or by a family that is exhausted by two shifts of work, is not a family emotional process, and a genogram will document the exhaustion and will not explain it.

The framework's own answer — the sociocultural emotional process — is the right answer, and it is under-developed. A practitioner who uses it will do better than one who does not, and the practical requirement is that the practitioner asks, of every family system, what is happening to it from outside: what is the housing like, what are the wages, what is the school system, what is the immigration status, what is the health service, what is the police presence on the street.

## 12.3 Ethical considerations

**Confidentiality and the family.** Working with a family raises the confidentiality question in its sharpest form. A young person who discloses something in an individual session may not want it shared with the family, and the system requires that what is said where is stated in advance, at the level of the specific.

**The young person's right to be heard.** The systemic view must not become a way of overriding the young person's account. The young person is a member of the system and not merely a position in it.

**The right to refuse family involvement.** A young person whose family is unsafe may be appropriately excluded from family work, and a practitioner who pursues family involvement in the presence of ongoing risk is doing harm.

**The use of the genogram.** The genogram must be constructed with the family and never presented to a young person as a document prepared about them. It must be stored securely, and it must be shared only with the people the family has agreed.

**Avoiding the appropriation of the theory for blame.** The most common ethical failure in systemic work is the deployment of the concepts in a way that assigns responsibility for a young person's difficulty to a family who are themselves the most damaged by the circumstances. The sociocultural process is the corrective, and the practitioner must be able to state what the family is up against.

**Power and confidentiality in the wider system.** A genogram may contain information about a family that is relevant to a safeguarding concern, and the practitioner must know the local reporting obligations and the limits of confidentiality in relation to them.

# 13. Key Terms

### Key Terms at a Glance

- **Family systems theory** — The tradition, developed from Bowen's work, in which the family is understood as a nested set of systems governed by the same emotional processes at different scales.
- **Differentiation of self** — The degree to which a person can maintain a clear sense of self within an emotional relationship, thinking, feeling, and acting in congruence with their own convictions.
- **Undifferentiation** — The flooding of thought, feeling, and action by the emotional pressure of a relationship, in which the person cannot think clearly, cannot modulate feeling, and acts rigidly or impulsively.
- **Cut-off** — The process of reducing emotional involvement with the family in order to reduce anxiety, at the cost of the emotional connection.
- **Healthy, internal, and external cut-off** — The three forms of cut-off: the psychological separation that permits functioning, the withdrawal of emotional availability within the family, and the severance of the relationship.
- **Two-person system** — The dyadic relationship, which Bowen identified as the primary unit of emotional life.
- **Triangle** — A three-person system in which tension between two people is relieved by the involvement of a third; the site of nearly all emotional conflict.
- **Comfortable triangle** — A triangle in which the third person is in tension with both others.
- **Conflictful triangle** — A triangle in which the third person is in tension with one side and aligned with the other.
- **Just relationship** — A relationship of contact and mutual support maintained at a low level of emotional intensity; a principal clinical target in adolescent work.
- **Intense relationship** — A relationship characterised by fusion, high emotional intensity, and difficulty in maintaining a defined self.
- **Law of the preservation of self** — The principle that the function of the organism is to preserve its own integrity and to function as a whole.
- **Law of the preservation of the family** — The principle that the emotional system of the family is more important than any individual member of it, and the source of the tension with the first law.
- **Nuclear family emotional process** — The transfer of emotional process from one generation to the next through the parental subsystem.
- **Family projection process** — The transmission of the parents' own unresolved emotional material to a child, and its introjection by the child.

### Key Terms at a Glance (continued)

- **Projection** — The transmission of the parents' unresolved issues, attitudes, and emotional needs onto a child.
- **Introjection** — The child's absorption of the projected material into their own emotional structure.
- **Multigenerational transmission process** — The description of how emotional processes are transmitted across generations through the family projection and the emotional cutoff.
- **Sibling position** — The way in which a child's place in the birth order, the age gaps, and the sex composition shape the family emotional process.
- **Genogram** — A family diagram that records the relationships, the emotional process, and the significant events across three or more generations.
- **The genogram levels** — The concentric levels of the genogram: the social, the psychological, and the medical.
- **Genogram construction** — The clinical procedure of drawing the family diagram with the family, over four to five sessions, structure first, then relationships, then emotional process.
- **Sociocultural emotional process** — The way in which the emotional processes of a family are shaped by the wider culture, and by the material and political conditions in which it lives.
- **Family emotional system** — The overall organisation of the emotional processes of the family.
- **Emotional process in the body** — Bowen's observation that family members' bodies synchronise in the presence of emotional tension, making the body a diagnostic instrument.
- **The family member who refuses to participate** — The young person who declines to attend family work, whose refusal is itself a systemic communication with a small number of identifiable meanings.
- **Cut-off in adolescence** — The young person's withdrawal from a parent, understood as a possible protection from an intolerable fusion rather than as a character defect.
- **Three-generation focus** — The Bowenian practice of working with a family across at least three generations, so that the current difficulty is located in a lineage rather than in a person.
- **The genogram as a shared object** — The use of the genogram as a clinical instrument that the family can look at and discuss together, rather than a document prepared about them.
- **Chronic family problem** — A problem that has been transmitted across generations and is maintained by the family's current emotional process.
- **Sequential in time** — The Bowenian view of a family problem as a sequence over time, in which the current presentation is one moment in a process.

**Key Terms at a Glance (continued)**

- **The family projection of sibling position** — The tendency for a child who occupies the position of a parent's own sibling to receive an intensified projection.
- **Intergenerational continuity** — The transmission of emotional patterns across generations, which the theory treats as the primary clinical subject.

## 14. Chapter Summary

Bowen family systems theory is a framework in which the family is the fundamental unit of emotional life and in which the same processes operate at every scale, from the two-person dyad to the culture. Its eight core concepts are the two-person system, the differentiation of self, triangles, nuclear family emotional process, emotional cutoff, the multigenerational transmission process, the family projection process, and sibling position, with the sociocultural emotional process and the family emotional system completing the framework.

Differentiation of self is the central clinical concept, and the chapter developed it carefully: the capacity to think, feel, and act in congruence with one's own convictions within an emotional relationship. The two poles were described, the undifferentiated position and the cut-off position, and the chapter was explicit that neither is the goal and that a differentiated position is characterised by the capacity to be close and to be autonomous at the same time. Differentiation operates intrapersonally, in the distinction between the facts and the interpretations, and interpersonally, in the capacity to hold two views of a child at once.

The governing laws were stated and their tension explained, with the explicit caution that the theory does not counsel self-sacrifice or family loyalty, and that the resolution of the tension is called differentiation. The clinical significance was then derived: a family with a symptomatic young person typically contains at least one undifferentiated member and at least one cut-off member, and the symptom reduces as the family's differentiation increases.

The chapter treated the triangle in detail, because almost all clinical material with a young person is triadic, and because the four clinical consequences of the triangle are the practical heart of the theory: that the symptom stabilises the triangle, that removing a symptom without replacing the structure releases the tension, that every conflict between two people has a third, and that the adolescent's position between two parents is a developmental fact. The just relationship was described as the principal target of the work.

The nuclear family emotional process, the emotional cutoff, and the family projection process were described as the mechanisms of the intergenerational transmission, with the family projection process explaining the over-responsible young person whom the theory identifies as one of its most recognisable presentations. The genogram was presented as Bowen's most widely borrowed clinical instrument, with its three levels, its four-session construction procedure, its three distinct uses, and its three limits.

The work with young people was developed in terms of the developmental fit, the clinical principles, the four-session sequence, and the case of the young person who will not come, with the family member who refuses to participate given the specific and clinically useful answer that Bowenian practice offers.

The case of Ruth demonstrated the whole framework. Her symptoms were located in a family projection process operating across two generations, visible on a single page; the work with the parental subsystem was the essential work; the genogram was used to make the family look at the pattern rather than at the symptom; and the outcome measure that mattered — that nobody falls over — was a measure of the family's capacity to hold itself together.

The evidence was presented honestly: there is no substantial controlled outcome research on Bowenian family therapy as a whole, the family-based treatment literature is stronger than the theory-specific literature, and the theory's most defensible contribution is to the organisation of clinical thinking rather than to measurable outcomes. The strengths and limitations were set out, and the limitations included the empirical thinness, the circularity risk, the presupposition of a family, the risk of absolving the family of accountability, and the difficulty of learning and supervising the work.

The cultural analysis addressed the culturally specific definition of the family, the cultural patterning of the family emotional process, the intergenerational respect for elders, and the migration and displacement of families, and the sociopolitical critique was stated at full strength: a family system that is exhausted by two shifts of work is not a family emotional process, and the sociocultural process is the corrective that the framework under-develops. The ethical section addressed confidentiality in the family system, the young person's right to be heard and to refuse family involvement, the use of the genogram, the appropriation of the theory for blame, and the power implications of a document that contains a family's history.

## 15. Review and Discussion Questions

**Review and Discussion Questions**

1. Explain the clinical observation that produced the family therapy movement.
2. State the eight core concepts of Bowen's family systems theory.
3. Explain what it means that the framework is scale-invariant, and give an example at three levels.
4. State the two governing laws and explain their tension.
5. Define differentiation of self, and distinguish it from independence, autonomy, and emotional detachment.
6. Describe the undifferentiated and the cut-off positions, and explain why neither is the clinical goal.
7. Distinguish intrapersonal from interpersonal differentiation, with an example of each.
8. Explain the clinical significance of the family member who is most involved and the family member who is cut off.
9. Describe Bowen's observation about the body, and state its three practical consequences.
10. Define a triangle and distinguish the comfortable from the conflictful form.
11. State the four clinical consequences of the triangle, and explain the significance of the third.
12. Explain the just relationship and its role as a clinical target.
13. Describe the nuclear family emotional process and what is transmitted in it.
14. Distinguish the three forms of emotional cutoff and the clinical consequence of each.
15. Describe the family projection process and the presentation it produces.
16. Explain the clinical significance of the sibling position propositions, and the caution about them.
17. Describe the genogram, its three levels, and its four-session construction procedure.
18. State the three uses of the genogram and its three limits.
19. Explain the developmental fit of Bowenian thinking with adolescence.
20. State the six clinical principles of Bowenian work with young people.
21. Describe the four-session clinical sequence and the purpose of each session.
22. Explain the answer that the family systems tradition gives to the young person who will not attend.
23. Describe the case of Ruth and state the three features of it that generalise.
24. State the status of the evidence for Bowenian family therapy, and summarise the family-based treatment literature.
25. State the three limitations of the evidence base.
26. State the six strengths and the five limitations of the framework.

**Review and Discussion Questions (continued)**

27. Explain the four cultural assumptions of the framework and the cost of ignoring them.
28. State the sociopolitical critique and the framework's own answer to it.
29. State the six ethical requirements for systemic work with young people.

## 16. Practice Activities

**Practice and Application**

### Activity 30.1 — Drawing a Genogram (120 minutes, individual)

Draw a three-generation genogram of your own family, using the standard symbols. Record the structure, then the relationships, then the emotional process, then identify the triangles, the cut-offs, and the projected material. Then write two paragraphs: one describing the pattern you found, and one describing the one thing you found that you had not previously known about your own family. The second paragraph is the point of the exercise, and students consistently report that it is the exercise that changes how they think about their own professional history.

### Activity 30.2 — The Triangle Analysis (75 minutes, small group)

In groups of three, take a real case from placement and map every triangle in it: who is in conflict with whom, and who is the third. Draw each triangle. Then identify the symptomatic member and mark the position they occupy in each. Finally, answer the question the theory asks: "who is the third?" for three separate conflicts in the case, and check your answers against the family. Most groups find that the answers are surprising and that the family can confirm them immediately.

### Activity 30.3 — The Genogram Conversation (90 minutes, triadic)

One student plays a sixteen-year-old who has been told that the family "has problems" and who is wary of the exercise; one plays the mother, who is relieved to be asked to talk about her own history; one plays the practitioner, who draws the genogram and asks the questions. The practitioner's task includes asking about the grandmother's own childhood, and handling the moment when the mother becomes upset. The exercise teaches two things that reading cannot: that the genogram is experienced as an invasion or as a relief depending on the family, and that the young person is usually the most suspicious participant and the one who gains most.

### Activity 30.4 — The Sociocultural Audit (60 minutes, individual)

Take a case from placement and write the two accounts. The first is the genogram account: the emotional process in the family, the triangles, the transmission. The second is the sociocultural account: the housing, the income, the shifts, the school, the immigration status, the health service, the transport, the policing. Then write the two paragraphs side by side and assess how much of the first account is actually explained by the second. Students who do this exercise regularly find that a substantial proportion of what looked like a family pattern is a consequence of material conditions, and this is the most important lesson in the chapter.

## 17. Annotated Reading Pathways

**For the theory.** Read Bowen (1976) for the clearest statement, and read Bowen (1978) for the clinical applications. Then read Bishop (2012) for the practice, and Shapiro (2018) for the clearest modern exposition.

**For the instrument.** Read Bowen (1968) for the original paper and then McGoldrick and Randy (2015) for the assessment application. The genogram is a skill that is learned by doing, and the readings support the practice rather than substitute for it.

**For the field.** Read Nichols (2013) for the whole of the family therapy field, including the schools that Bowen did not found, and read Goldenberg and Goldenberg (2013) for the broad orientation. Reading the field's diversity is what prevents the mistake of treating Bowenian theory as the family therapy field.

**For the evidence.** Read the family-based treatment literature on adolescent eating disorders and on adolescent substance use, and read the multisystemic therapy evidence. These are the studies that actually support the claim that parental involvement matters, and they are more useful to a practitioner than the theory-specific research.

**For the critique.** Read the critical literature on the family systems tradition and on the social construction of family dysfunction, and read the evidence on structural inequality and adolescent mental health. The combination of the two is the preparation for the sociocultural work that the framework needs and does not supply.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Family Systems Theory: Bowen and the Generational Project** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is differentiation, triangles, nuclear family emotional process, and the genogram as a clinical tool. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is family patterns, attachment, boundaries, communication, stories, and relational resources. The mechanism to keep in view is how interaction sequences and shared meanings distribute distress, protection, responsibility, and possibility across a system. The characteristic professional risk is blaming families, exposing a young person in unsafe joint sessions, or ignoring material conditions and individual needs. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in family meetings, school consultations, care networks, and individual sessions informed by systems thinking, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable,

and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Daniel is fifteen and is seen in an integrated school and health team for conflict with parents about autonomy. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Daniel's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Daniel explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is

expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on family patterns, attachment, boundaries, communication, stories, and relational resources. The first intervention is deliberately modest. Daniel chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Daniel has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Daniel can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.

- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Family Systems Theory: Bowen and the Generational Project

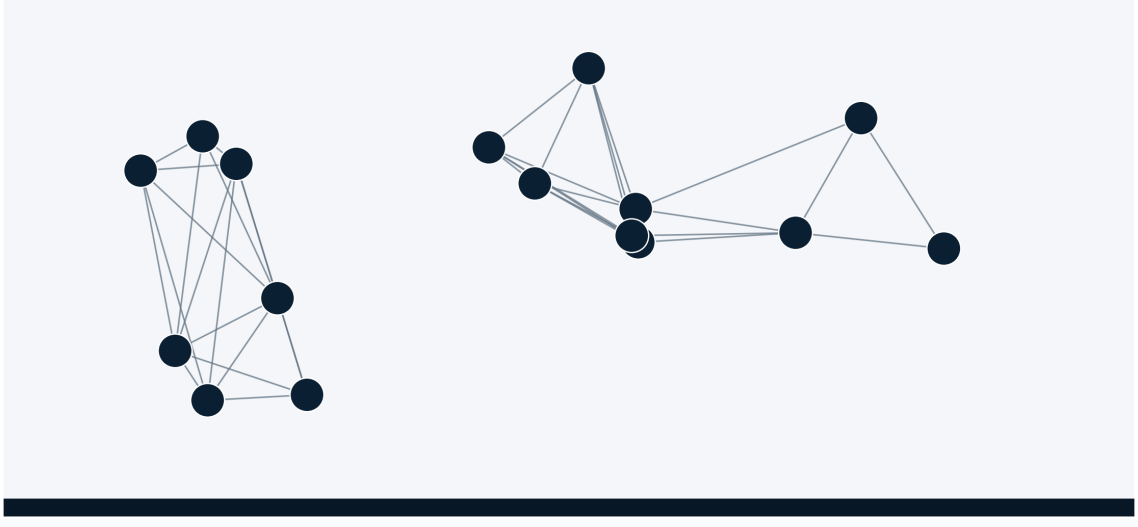
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Family Systems Theory: Bowen and the Generational Project** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Family Systems Theory: Bowen and the Generational Project** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Family Systems Theory: Bowen and the Generational Project**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Family Systems Theory: Bowen and the Generational Project to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 31

# Structural Family Therapy

Minuchin's structural model, boundaries, subsystems, and restructuring with adolescents and parents.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the development of the structural model within the family therapy movement and state the clinical problems that produced it.
- Define the five key structural concepts: structure, subsystems, boundaries, hierarchy, and family projection process.
- Explain the concept of the family structure and distinguish it from the family interaction pattern.
- Describe the structure of a family in terms of subsystems, boundaries, and hierarchy, and construct a structural map of a real family.
- Explain the concept of boundaries and their three types, and describe the boundary problems that appear in clinical work with adolescents.
- Describe the principles of structural family therapy, including the use of the structural map, the enactment, the challenge, the restructuring, and the maintenance of change.
- Apply the structural model to a case involving an adolescent and a family, and evaluate the limits of the model.
- Critically evaluate the cultural and ethical dimensions of structural family work with young people.

## Chapter Overview

The structural model was built on a clinical observation that is now so familiar it is easy to miss: **the family is a structure, and the symptoms are structural in origin.**

Salvador Minuchin and his colleagues at the Philadelphia Child Guidance Clinic came to this through work with families of severe, entrenched, and chronic difficulty — families in which the identified patient's symptoms had been present for years, in which previous treatment had not helped, and in which the family appeared to be organised in a way that produced the symptom and resisted any change that did not alter the organisation. The structural therapists' claim was that a symptom in such a family is not an expression of intrapsychic conflict and not a learned behaviour, but a **consequence of the family's structure** — of who is in which subsystem, of where the boundaries are drawn, and of who is in charge of whom.

The model's central intervention is a **restructuring** of the family's organisation, and its central clinical skill is the **enactment**: the invitation to the family to do, in the consulting room, the thing they typically do outside it, so that the practitioner can see the structure in operation rather than hear about it. The enactment was the single most important contribution of the structural school to the technique of family therapy, and it has been adopted, in one form or another, by almost every subsequent school.

The model is a good fit for the work of this book. Adolescents present with structural problems in a way that younger children do not, because the adolescent's developmental task is a reorganisation of the family system, and the structural therapists' concepts of hierarchy, of boundary renegotiation, and of the move from the child subsystem to the adult subsystem are, in effect, descriptions of that task. The problem-solving therapy and the boundary work of the model map directly onto the developmental work of adolescence.

The model's limitations are also worth stating at the outset. The structural model is the least culturally responsive of the family therapy theories, because it assumes a nuclear family, a parental authority structure,

and a set of developmental expectations that are not universal. In Chapter 48, the cultural analysis of the family therapies is taken up in full.

# 1. Historical Context

## 1.1 The Philadelphia Child Guidance Clinic

Minuchin trained as a paediatrician and as a psychiatrist, and his clinical work was at the Philadelphia Child Guidance Clinic, where he led a training programme in family therapy that was the most rigorous in the field for two decades. The clinic's caseload was distinctive: children with severe behavioural and emotional problems, families in which the difficulty had usually been present for years, and families who had been through the child guidance and the individual therapy literature without benefit.

The clinical pressure of that caseload produced the structural theory. If a child's symptom has been present for years, has resisted individual treatment, and is embedded in a family that has developed an elaborate and effective organisation around it, then the organisation is the clinical fact, and the work must be directed at the organisation.

## 1.2 The two problems the model solved

**The problem of the "chronically ill" family.** Minuchin described a family in which a member has been designated as the sick one, and in which the family has organised itself around that designation: the routes of communication are narrowed, the parental roles are reduced, the siblings are conscripted into caretaking or into alignment with the identified patient, and the family has become a stable system whose stability depends on the continuation of the symptom. A treatment that does not restructure the system will produce a change in the symptom followed by its return, because the system has been designed to reproduce it.

**The problem of the "temporarily ill" family.** A second pattern, in which the identified patient is in a position that is transiently untenable — a child who has been assigned a role he cannot sustain, a family in which a parent has been left in charge of both the practical and the emotional management of the children — and in which the symptom will resolve when the structure is corrected.

## 1.3 The relationship to the other schools

The structural model emerged at the same time as the strategic and the Bowenian models, and the three share a premise — that the individual is not the unit of treatment — while differing in what they take to be the primary thing to change. The structural school changes the **organisation**. The strategic school changes the **sequence of interactions and the beliefs about the problem**. The Bowenian school changes the **emotional process and the differentiation**.

The distinctions are worth keeping clear because each generates a different clinical conversation. A structural conversation is about who talks to whom, who decides, and who belongs with whom. A strategic conversation is about the sequence in which things happen and about the attribution of responsibility. A Bowenian conversation is about intensity, differentiation, and the multigenerational pattern.

## 1.4 The development of the model

Minuchin's original formulation was developed with, and refined alongside, his colleagues — particularly Berry, Nagel, and others at the Philadelphia clinic — and it was given its definitive statement in Minuchin's 1974 book *Families and Family Therapy* and its structural-developmental statement in Minuchin's 1978 paper on the structural family treatment of the delinquent adolescent.

Two later developments matter for this book. The first is the **integration of the structural model with the attachment and developmental research** of the 1980s and 1990s, which supplied the developmental criteria for the tasks of the subsystems and made the model more usable with young people. The second is the **development of the structural model with families in poverty and in structurally disadvantaged circumstances**, which is the direction in which the model's assumptions have been most challenged and most usefully revised.

## 2. The Five Key Concepts

### 2.1 Structure

**Family structure** is the organisation of the family, characterised by two features.

**The structure is defined by the subsystems, the boundaries, and the hierarchy**, which are described below.

**The structure is defined by the family's pattern of interaction**, which is the observable and reportable behaviour of the family members: who talks to whom, who is included in what, who defers to whom, who initiates and who responds.

The distinction between the structure and the interaction pattern is important and is a common source of confusion. The interaction pattern is what the family does; the structure is the organisation that the pattern reflects and maintains. A family in which the father speaks to the mother and never to the daughter has an interaction pattern; the structure is the arrangement in which the father is the sole conduit of information and authority to the daughter, and in which the daughter is a member of the child subsystem that is functionally excluded from the adult subsystem.

### 2.2 Subsystems

A **subsystem** is a group of two or more people in the family who are more closely involved with each other than with the others, and which therefore develops its own rules, its own functions, and its own boundaries. Structural therapists have conventionally identified three in the nuclear family, and the terminology is worth using carefully.

**The individual subsystem** is the person.

**The sibling subsystem** is the group of siblings, and it is the unit in which the peer relations of the family are organised. In families with adolescents, the sibling subsystem is often the site of the most active boundary negotiation, and it may be the alliance in which the adolescent's separation is first attempted.

**The parent subsystem** is the marital or spousal unit, and in a family with adolescents this is the unit whose relationship with the child subsystem determines most of what happens.

Two subsystems may be **discrete** — clearly bounded from each other, with no crossover — or **nurturing** — clearly bounded in some respects but with permeability in others, which allows the flow of affection, support, and information while preserving the distinctness of the units.

## 2.3 Boundaries

**Boundaries** are the invisible lines of influence and responsibility that separate the subsystems and the individuals within them. They are the structural model's most important clinical concept, and the one that maps most directly onto the clinical problems of adolescence.

Three kinds of boundary appear in the clinical description.

**Diffuse boundaries** are indistinct, permeable, and non-defining. A person with a diffuse boundary has difficulty differentiating what belongs to them from what belongs to others; the other person's thoughts, feelings, and actions are experienced as their own; and the person is over-involved in others' lives and is unable to act independently. In the family context, diffuse boundaries appear as a parent who cannot allow a child to have an experience that is not shared with her, or a young person who cannot say what he thinks without checking what his mother thinks.

**Clear boundaries** are defined, appropriate to the developmental stage, and permit the flow of affection and support while maintaining the distinctness of the subsystems. A clear boundary between a parent and an adolescent allows the parent to care for the adolescent and to be involved in his life while also allowing him to be his own person, to have private thoughts, and to have relationships the parent does not enter.

**Rigid boundaries** are impenetrable and restrictive, and are typically the result of a history of premature autonomy, of trauma, or of a family in which closeness itself has been experienced as dangerous. A rigid boundary between a parent and an adolescent produces a young person who is emotionally isolated, self-sufficient, and unable to ask for help, and the young person's difficulty in asking for help is frequently mistaken for strength.

## 2.4 Hierarchy

**Hierarchy** is the clear line of authority across the subsystems. The structural model's position is that the parents are in charge of the children, and that the children are not in charge of the parents, and that a family in which the hierarchy is inverted produces symptoms in the children.

The three forms of hierarchy disorder are worth naming.

**Parentification** occurs when a child takes a parental function, either by taking over a practical role — the cooking, the shopping, the care of the siblings, the management of the household — or by taking over the emotional role, by becoming the confidant and the comforter of a parent. Parentification is the structural description of the "over-responsible child", and it is the single most common structural problem in the clinical literature on adolescents.

**Parentification may also run the other way**, in which the parent becomes the child — the parent who confides in the adolescent, who asks the adolescent for advice, who relies on the adolescent for emotional support, or who becomes so focused on the adolescent's needs that the adolescent becomes the caretaker of the parent's emotional life. Minuchin described this as the parent and the child becoming "inverted" in the hierarchy.

**Sibling inversion** occurs when a sibling takes a parental function over another sibling, and it is very common in families with a disabled or distressed child, and it creates a bond that is difficult to dissolve later.

## 2.5 The family projection process

The structural model adopted the family projection process from Bowen, and it uses it in a specifically structural way: the projection of the parents' own difficulties onto a child, and the child's structural role in the family being shaped by that projection.

The clinical significance in the structural frame is that the projected child is usually also the structurally positioned child. A mother who is unable to tolerate her own anxiety projects it onto a child who is placed in a role that requires her to manage it, and the child's symptoms are the medium of the projection.

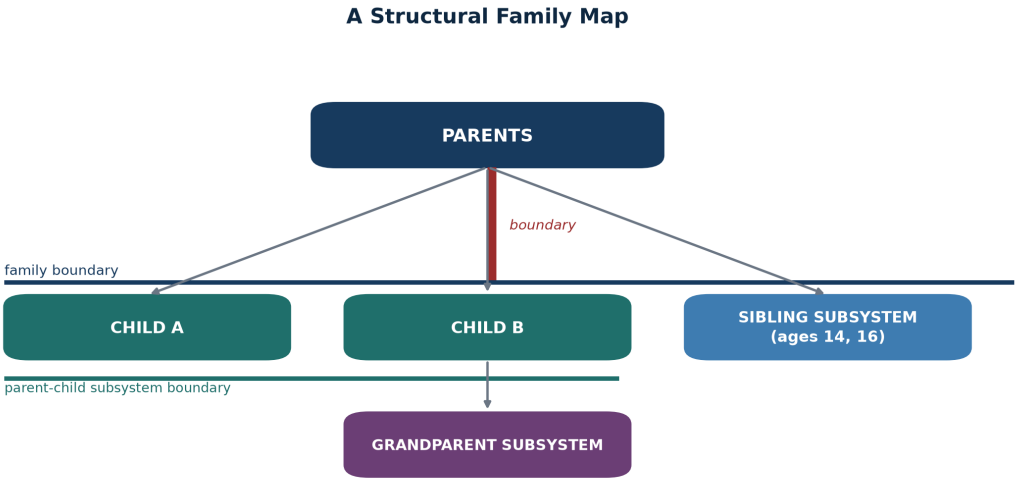


**Figure 31.21** A structural family map showing the parent subsystem, the child subsystem, the sibling subsystem, and the extended family, with the family boundary, the parent-child subsystem boundary, and the generational hierarchy marked.

# 3. Structural Diagnosis

## 3.1 The procedure

The structural diagnosis proceeds in four stages, and it is done with the family present.

**Stage 1: the presenting problem.** The referral question is recorded, and the practitioner asks the family to describe the problem in their own terms. The question that is asked is not "why does she do that?" but "when does it happen, and what happens just before, and what happens just after?"

**Stage 2: the interaction pattern.** The family is asked to describe a recent ordinary occasion in detail, and the practitioner draws the sequence of who did what to whom. This is the "sequence" work, and it is the technique the strategic school also uses; the structural school asks the same question and uses the answer differently.

**Stage 3: the structural map.** The family is drawn in the form of the standard structural diagram, with squares for males and circles for females, with the subsystems delineated, and with the boundaries marked. The drawing is done in the session, with the family's corrections, and the corrections are as informative as the drawing.

**Stage 4: the diagnosis.** The practitioner names the structure: who is in which subsystem, where the boundaries are diffuse, clear, or rigid, where the hierarchy is inverted, and what the family projection process is doing.

### 3.2 The structural map as a clinical tool

The map is used in three ways, and the student should be able to distinguish them.

**As a diagnostic instrument.** The map makes visible the structure that the family cannot see, and the moment of seeing is often a moment of considerable emotional impact.

**As a communication device.** The map can be handed to a school, to a doctor, and to a new practitioner, and it communicates the structure in a form that a non-specialist can use. It is the most portable document in the family therapy field.

**As a therapeutic instrument.** The map is drawn with the family, and the drawing is itself the beginning of the change, because a family that has drawn its own structure has begun to see it.

### 3.3 The distinction between the structural and the interactional formulation

A student should be able to produce both formulations for the same case, because they are different products and they point to different interventions.

The **interactional formulation** describes the sequence: who does what, in what order, with what consequence. It is the basis of the strategic work in Chapter 32 and of the contingency management in Chapter 28.

The **structural formulation** describes the organisation: who is in which subsystem, where the boundaries are, and where the hierarchy is inverted. It is the basis of the structural work.

For the same case, the interactional formulation might be: "the mother withdraws when the daughter asks for anything, and the daughter escalates until she is answered." The structural formulation might be: "the mother and the daughter are in a diffuse boundary, with the daughter functioning as the mother's confidant and the mother functioning as the daughter's emotional regulator; the parental subsystem has collapsed because the father is absent and the grandmother has assumed the parental function with a rigid boundary towards the father."

The structural formulation is the one that predicts what will happen if the practitioner works only on the interaction.

## 4. The Principles of Structural Family Therapy

### 4.1 The first principle: the structure causes the symptom

The first principle is the organising claim of the model: the symptom is a consequence of the family structure, and the symptom will persist as long as the structure persists and will resolve when the structure changes. The clinical implication is that a treatment directed at the symptom alone will fail, and the treatment must be directed at the structure.

## 4.2 The second principle: the family is the unit of treatment

The family is the unit because the structure is the thing that must change, and the structure is not located in any individual. The structural therapists are not neutral about this, and the practice of seeing the family together is not a convenience: a practitioner who sees only the identified patient will be inducted into the family structure as it is, and will be positioned in it, and will be unable to work with it.

## 4.3 The third principle: the intervention is the restructuring

The aim of the intervention is to change the structure: to move a young person from the child subsystem to a position in which they are treated as an adult where the developmental stage requires it, to redraw the boundaries, to restore the hierarchy, and to alter the alliances.

## 4.4 Enactment

The **enactment** is the signature technique of the model and one of the great technical contributions of the family therapy field. It is the invitation to the family to perform, in the consulting room, the interaction that they typically perform outside it, so that the practitioner can observe the structure directly.

**The procedure.** The practitioner asks a family member to describe a recent instance of the difficulty, selects a segment of it, and asks the participants to "go through it" — to enact the exchange as it happened, with the roles they normally occupy and with the words they normally use. The practitioner observes.

**What the enactment reveals.** The practitioner sees the sequence, the alliances, the covert rules, the double binds, the invitations and the refusals. What the family can describe and what the family can *do* are different, and the difference is usually the clinical material.

**The interruption.** After a short time — often less than a minute — the practitioner interrupts, and the interruption is the intervention. The practitioner does not comment on the content; the intervention is behavioural and structural. The classic interventions are: the practitioner asks the young person to do what they have been unable to do; the practitioner asks the parent to stop doing what they have been doing; the practitioner comments on what the family has just demonstrated; or the practitioner enacts a small piece of the interaction themselves in order to make the pattern visible.

**The risk.** The enactment is a challenge, and it can be experienced as a humiliation, particularly if the practitioner interrupts at the moment of the young person's greatest distress, or in a way that sides with the parent against the young person. The structural therapists were not always careful about this, and the modern practice is to time the intervention with care and to attend to the young person's subsequent state.

## 4.5 Challenge and restructuring

The **challenge** is the general term for the interventions that the practitioner makes to change the family's organisation, and the structural therapists' challenge is characteristically direct: naming the process, naming the double bind, and refusing the invitation to be triangulated.

Some of the specific challenges are worth naming.

**The refusal of the triangulation.** When the young person is enlisted as the parent's ally or as the parent's rescuer, the practitioner declines the role and says so. This is the intervention that addresses parentification directly, and it is often experienced by the parent as a betrayal, and it frequently produces an immediate deterioration in the therapeutic relationship with the parent that is temporary and is the sign that the

challenge has landed.

**The naming of the double bind.** A double bind is a situation in which a person receives two incompatible messages, and the restriction on the communication of the message is itself part of the bind. A parent who says "you are an adult now, you make your own decisions" while also saying "if you don't do what I say, you don't respect me" has constructed a double bind, and a young person placed in a double bind is placed in a position from which any response is a symptom. The intervention is to name the bind to the parents, not to the young person.

**The boundary renegotiation.** The most important restructuring with an adolescent is the movement of the boundary between the parent-child subsystem and the adult subsystem. In most clinical work with adolescents, the parents are maintaining a pre-adolescent structure over an adolescent child, and the symptom is a report of the mismatch.

### 4.6 The maintenance of change

The structural therapists were unusually aware that the change achieved in a session decays, and the model has a good account of why: the change is a behavioural change in the family's organisation, and the old organisation is stable because it is familiar, because it is costly to change, and because the other members of the family have not been helped to accommodate the change. A young person who has been given more autonomy and a parent who has not adjusted to the new structure will find the change reversed within a fortnight, and the practitioner should expect it and plan for it.

Three technical requirements follow. The change must be **consensual** — every member of the family must have some stake in it, and a restructuring imposed from outside will be dismantled. It must be **explicit** — the new rules are stated aloud, in the session, and by the family, so that the new structure is a shared project rather than a secret. And it must be **maintained by the family's own mechanisms**, which in practice means the practitioner works with the parent on the parent's difficulties with the new structure, and the parent's difficulties are the material.

# 6. Structural Family Therapy with Children and Adolescents

## 6.1 The developmental fit

The structural model is unusually well matched to the developmental stage at which adolescents present, for four reasons that a student should be able to state.

**Adolescence is a structural task.** The adolescent's work is a reorganisation: the movement from the child subsystem to a position of increasing autonomy, the renegotiation of the parent-child boundary, the acquisition of a peer world that the parents do not control, and the eventual establishment of a life that is theirs. These are exactly the structural variables the model names.

**The mismatch is the pathology.** A family that maintains a pre-adolescent structure over an adolescent child produces a symptom. The symptom is the report of the mismatch, and it is a report in the language of behaviour because the young person does not have another channel.

**The parentification problem is developmentally salient.** A young person who is managing a parent's emotional life is being asked to do a developmental task in reverse, and the structural model has the clearest available language for it.

**The intervention is structural.** The restructuring of the boundary and of the hierarchy is precisely the intervention that the developmental task requires, and the model provides the technical means to do it.

## 6.2 The four structural tasks of adolescence

The structural-developmental formulation identifies four developmental tasks, and the assessment of an adolescent is organised around them. A student should be able to use them as a checklist and, more importantly, should be able to recognise a task that has been left incomplete.

**The first task: to differentiate from the family of origin while maintaining a relationship with it.** The failure of this task presents as either fusion — the young person cannot be apart — or cut-off — the young person cannot be together. A family that has not made room for the differentiation will find that the adolescent leaves entirely, or that the adolescent stays and cannot develop.

**The second task: to move from the child subsystem to a more adult position in the family.** This involves the renegotiation of the boundary, the assumption of adult responsibilities, and the participation in adult decision-making. The failure of this task presents as a young person who is treated as a child in the

family's structure and who responds with the only available means.

**The third task: to develop peer relationships of increasing depth and mutuality.** The family structure must permit the peer world, and the parents' difficulty in permitting it is usually a difficulty with their own fear.

**The fourth task: to develop a vocational and financial direction that enables leaving home.** This is a task that is often overlooked in clinical work with adolescents and it is a common source of family conflict that is misread as a behavioural problem.

## 6.3 Boundary problems in clinical practice

Four boundary presentations recur, and each requires a different intervention.

**The diffuse boundary.** The parent and the adolescent are so close that the parent's feelings are the adolescent's feelings and the adolescent's are the parent's. The clinical presentations are: the adolescent who cannot make a decision without checking with the parent; the parent who cannot tolerate the adolescent's distress and must resolve it immediately; and the adolescent who reports a sense of being responsible for the parent's emotional state. The intervention is the establishment of a clear boundary, which is painful and which is usually resisted by the parent, because the parent experiences the boundary as a loss.

**The rigid boundary.** The parent and the adolescent are separated, and the separation is usually the residue of something: an earlier closeness that ended in conflict, a loss, a previous family breakdown, a history of the parent being hurt by the same behaviour. The clinical presentations are: the adolescent who is emotionally unavailable, who does not share anything, who has no visible distress and who cannot be reached; and the parent who says the adolescent is "fine" and is puzzled by the referral. The intervention is a gradual increase of contact, and the risk is that the increase of contact re-ignites whatever produced the rigidity.

**The two-boundary problem.** The adolescent is closely enmeshed with one parent and rigidly distant from the other. This is the classic triangulated adolescent presentation, and it is very common where a family has separated or where one parent is absent. The intervention is directed at the parental subsystem and not at the adolescent, and a practitioner who works with the adolescent alone will achieve very little.

**The boundary that oscillates.** The family alternates between intense closeness and complete distance, and the adolescent learns that the distance follows the closeness. The oscillation is usually maintained by the parent's own unresolved process, and the intervention is the work with the parent, and the adolescent's stability improves when the oscillation stops.

## 6.4 The clinical sequence

**Session 1: the individual.** An assessment with the young person, alone. The purpose is to hear the young person's own account of the family and to establish a relationship that is not mediated by the parents. This session is a structural intervention in itself, because it establishes the young person as a person with a perspective that is not the family's.

**Session 2: the family, and the map.** The family session in which the structure is drawn. The practitioner asks the family to describe a recent instance of the difficulty and to enact it. The drawing of the map follows.

**Session 3: the challenge.** The intervention session, in which the practitioner names the structure, refuses the triangulation, and makes the restructuring explicit. These sessions are frequently uncomfortable and frequently produce a temporary deterioration in the relationship with one or both parents, and the practitioner should be prepared for it and should have said in advance what will happen.

**Session 4 onwards: the maintenance.** The work with the parents on the new structure. The young person is seen individually and the family is seen together, and the balance depends on the case.

### 6.5 Work with the parents when the young person will not attend

A common situation is an adolescent who refuses to attend family sessions. The structural model has a clear answer, and it is more pragmatic than the Bowenian one.

The practitioner works with the parents alone, and the adolescent's absence is treated as a piece of structural information rather than as an obstacle. The parents are asked what the adolescent says about coming, and the answer is usually a statement about the family rather than about the therapy: "she says you'll take her side", "he says we'll all just criticise him", "she says you always talk about her when she's not there." Each of these is a description of a structural problem, and each of them can be worked with.

The practitioner also keeps a direct channel open with the young person, and the most useful practical step is often to shift the individual work to a different setting — a school, a text message, a walk — so that the young person is not in a position in which attendance means entering a structure they have named as unsafe.

## 7. Case Illustration: The Young Man Who Was Not Allowed to Grow Up

**Presentation.** Declan is sixteen and lives with his mother, his father, and a younger sister of eleven. He is referred by the school for "oppositional behaviour and possible ADHD". His mother attends the first appointment and describes a young man who is argumentative, who does not do his chores, who does not do his homework, who is in his room with his door shut, and who is "not the son I raised".

**The individual session.** Declan's own account is different. He describes a household in which he is the family's electrician, the family's driver, the family's shopper, the person who deals with the boiler, the person who looks after his sister when his mother works, and the person who is told to be "a man" by his father and not to be "a baby" by his mother. He says his mother rings him from work when the heating breaks. He says his father has never once asked him about school. He says that if he wants to go to a friend's house he has to have a reason and a time and a plan for getting back.

He also says something that reframes the referral: "You know what the problem is? There's no room for me to be fifteen. I'm either a little kid or I'm a man. There's nothing in between."

**The family session and the map.** The family is invited in and the practitioner asks each of them to describe a recent instance of the difficulty, and the family cannot agree. Declan's father describes an incident last week in which Declan did not come down for dinner. His mother describes an incident in which Declan did not answer the phone when she called from work. Declan describes a different incident entirely, in which his father told him he would be "kicked out" for coming home late.

The practitioner then asks the family to enact the most recent of these, and the mother begins to describe the phone call, and Declan's voice immediately changes, and he says, in a flat and sarcastic register, "I can't do anything right, can I?" — and the practitioner observes the father's immediate shift from the sofa to

standing, and the mother's hand going to her mouth, and the whole family reorganising around a fifteen-year-old's sarcastic sentence.

The practitioner interrupts at that point and says: "What I see is that Declan said one sentence and the three of you changed. Declan, what did you want to happen when you said that?" Declan says: "I wanted him to sit down." The practitioner asks his father whether he sat down. He did not. Declan says: "That's what I mean."

**The structural map.** The map is drawn in the session, and it looks like this. There is a parental subsystem in which the mother and the father are joined by a boundary that is diffuse at the point of contact with Declan and rigid at the point of contact with each other. There is a child subsystem of Declan and his sister, in which the siblings are close. The critical feature is between the parents and Declan: the boundary is *clear* in the direction of responsibility and *diffuse* in the direction of emotional involvement, and the map shows this as a line that is solid on one side and dotted on the other.

The projection process is also visible. Declan's mother is a single parent of a nine-year-old sibling when Declan was born, and the grandmother was the primary carer for the first three years. The grandmother died when Declan was four, and the mother describes having been "in pieces" for a year. The father met the mother when Declan was five and has never, by his own account, known how to talk to him; he says "I've never been one of those dads who does the talking." The projection of the grandmother's caretaking onto the mother, and the mother's fear of the loss of another person, are being carried into Declan's role as the family's competent one.

**The formulation.** Declan is not oppositional. He is *parentified*, and the parental subsystem is *collapsed in its parental function*, with the grandmother's function having been taken over by Declan. The family's difficulty is that the adult roles were never re-established after the grandmother's death, and the structure has been maintained for twelve years by the most efficient possible arrangement: the oldest child does it.

The symptom — the argumentativeness, the sarcasm, the closed door, the refusal to do homework — is the report of a young person who is a functional adult in a family that will not let him be fifteen.

**The intervention.** Four elements, and the sequencing matters.

*Element one: the parental subsystem.* The practitioner works with the parents alone for the first four sessions, and the work is not about Declan at all. The first session establishes that they have not spoken to each other about anything other than the children and the bills since Declan was five. The second session addresses the father's account of his own history with his own father, which is a short, angry, and revealing account, and the third addresses the mother's, which is a long account of a loss and of a household that held itself together. The fourth session is a joint session in which the practitioner asks them to describe each other's difficulties, and asks them to say it to each other rather than to him. It is a difficult and unglamorous session and it is the essential one.

*Element two: the boundary renegotiation.* The restructuring is specific and it is written down. Declan will have his own room and his own door, which will be closed when he wishes, and the family will not comment on it. Declan will have one evening a week when he is responsible for a specified household task, and the other two evenings his mother and his sister will manage without him, and this is the hardest part of the plan for the mother. Declan will not be the emergency contact for the heating, the shopping, or the school, and the practitioner will say this to the family explicitly and will then say why: "You have been running this house with a twelve-year-old in a man's job and it has nearly worked. It cannot go on, and it is not fair to him, and I am not going to let the household fail when it happens, so we are going to plan for it."

The practitioner says the last part in the family session, in front of Declan, because the unspoken fear is that the family will collapse when Declan stops, and saying it aloud is what makes the restructuring possible.

*Element three: the father's role.* The father's role is specified and it is small. One specific task, done on a specific day: he will drive Declan and his sister to the football match on Sunday, and they will go to the cafe afterwards, and this is a routine, and routines do not require intimacy. The practitioner explains to the father that Declan does not want a relationship that is emotionally intense; he wants a relationship that is predictable and does not require him to perform.

*Element four: the individual work with Declan.* Declan is seen throughout. The work is about the anger, which is enormous and is entirely justified, and about the difference between the anger at his family and the sarcasm, which is a defence that costs him the room he is in.

**The outcome.** At four months, Declan is still argumentative and is markedly less sarcastic. The chores are done, mostly, and the household tasks have been transferred with two significant relapses, both of which occur when his mother is under pressure at work and both of which are workable. The father and the son have a Sunday routine and have had three arguments in it, which the father reports as "progress, she says". The mother reports that she is "exhausted but different".

**The interpretation.** The case illustrates the structural model almost completely. The symptom was structural in origin. The intervention was a restructuring of the boundary, of the hierarchy, and of the parental subsystem, and the individual work with Declan was necessary and was not sufficient. The single most important moment in the whole case was the practitioner's refusal to allow the family to collapse silently, and the naming of the fear in front of the young person. A practitioner who had worked only on Declan's sarcasm, or only on his mother's anxiety, or only on the father-daughter relationship would have achieved a fraction of what was achieved.

# 8. Evidence and Research Support

## 8.1 The status of the evidence

The structural model has a modest evidence base, and the specific findings are as follows.

**There is no strong controlled evidence for structural family therapy as a whole.** The model's own tradition is more clinical than experimental, and the outcome literature on the specific model is limited.

**The evidence for family-based treatment of adolescent eating disorders is strong**, and the family-based approaches in this area share the structural premise that the parents must be restored to a central and authoritative position in relation to the young person's eating and that the parentification of the mother by the daughter must be interrupted. The family-based approach to anorexia nervosa and to bulimia nervosa is one of the clearest demonstrations in the field that a structural change in the family produces a change in the symptom.

**The evidence for behavioural family therapy for conduct problems is strong**, and the behavioural family therapy protocols are the most thoroughly validated family interventions for oppositional and conduct disorder. They are not structural family therapy, but they are family interventions with a clear structure: the parents are the agents of change, the child is the target, and the parent-child interaction is the medium.

**The evidence for multisystemic therapy is strong**, and the model is a systemic intervention with the same core premise.

**There is modest evidence for structural family therapy with child and adolescent conduct problems**, from a small number of controlled trials, and the results are more variable than those of the behavioural approaches.

### 8.2 What the evidence cannot settle

The question of whether structural family therapy is better than other family approaches is largely unanswerable, because the models are rarely compared and the therapists who practise them are rarely the therapists who evaluate them. The honest position is that the model provides a coherent account and a set of techniques, and that the specific interventions within it have variable support, and that the practitioner should be clear about which of their interventions are evidence-supported and which are technique.

### 8.3 Limitations of the evidence

**Small samples and high allegiance.** The family therapy literature has among the highest allegiance effects in the field, and the structural tradition has been particularly prone to a strong theoretical commitment.

**Proximal outcomes.** The family therapy literature overwhelmingly measures the resolution of the identified symptom, the family functioning, and the satisfaction of the referrer, and rarely measures the distal outcomes.

**The problem of the "response of the identified patient".** In family research, the young person's own account of improvement is often excluded in favour of the parents' account, on the grounds that the parents are more reliable. This is a serious methodological error in a field whose subject is the family, and it has been corrected in the more recent literature.

## 9. Strengths and Limitations of the Structural Model

### 9.1 Strengths

**It identifies a cause that can be changed.** The model's claim that the structure causes the symptom is unusual in psychotherapy, and it is a claim that points directly at something that can be worked on.

**It gives a clear description of the pathology.** A practitioner who can say "the parental subsystem has collapsed and the child is functioning as a parent" has a description that is immediately useful, that the family can understand, and that predicts what will help.

**It has a technical repertoire.** The enactment, the challenge, the map, the boundary renegotiation, and the maintenance of change are specific and teachable.

**It fits the adolescent developmental task**, as described above.

**It is compatible with other modalities**, and the structural work is frequently combined with behavioural, cognitive, and attachment work.

**The map is a portable document** that can be used with a school, with a new practitioner, and in a referral.

### 9.2 Limitations

**It is culturally narrow.** The assumptions about the nuclear family, the parental authority, and the appropriate developmental path are specific to a particular cultural context, and the model's language of hierarchy and of parental responsibility carries implicit value judgements that do not transfer.

**It can be used to enforce conformity.** The model's language of the parent's authority and of the child's place can be deployed in ways that are not therapeutic at all, and the boundary work of Chapter 48 is required to prevent this.

**The challenge can be a confrontation.** The structural therapists' willingness to interrupt an enactment in the moment of the young person's greatest distress was, in retrospect, too confident, and the modern practice is more careful about the timing and the aftermath of the intervention.

**It under-accounts for the individual.** A young person who is depressed, or autistic, or has a trauma history, has difficulties that are not structural, and a model that explains everything structurally can obscure them.

**The evidence is modest**, and the model has been rather poorly served by the research literature.

# 10. Cultural and Ethical Considerations

## 10.1 The cultural assumptions of the model

The structural model embeds a set of assumptions about family life that are not universal, and a student who does not examine them will impose them.

**The nuclear family with two parents.** The model assumes a parental subsystem, and the assumption fails for single-parent families, for families with three or more generations, for separated and never-married parents, for adoptive families, for families with a same-sex couple, and for families in which the kinship system is the extended family or the community.

**The hierarchy.** The model's position that the parents are in charge of the children is a position about parental authority, and parental authority varies enormously across cultures, families, and the contexts in which the young person lives. In some families and communities, the elder generation has authority and the parents do not; in some, the young person is expected to be self-managing from an early age; in some, the family's decisions are made collectively.

**The developmental path.** The structural-developmental formulation assumes a particular sequence: dependence, then differentiation, then autonomy, then leaving. Many young people follow a different sequence, and a family that does not follow the assumed sequence is not thereby pathological.

**The concept of the boundary.** The boundary metaphor is powerful and it is culturally specific. In cultures in which the self is understood as relational, in which interdependence is a value and not a failure of differentiation, the "too close" language of the model is a poor fit, and a family that is described as fused may simply be a family that functions well.

## 10.2 The risk of the model's misuse

The most serious risk in the application of this model is that it becomes an instrument of enforcement. The language of hierarchy, of the parent's authority, and of the child's place is readily turned into a justification for controlling a young person's behaviour, and the model's technical vocabulary lends an authority to that claim that it does not deserve.

Three safeguards follow. The practitioner should be alert to the moment when the work stops being about the young person's development and becomes about the parents' control of the young person. The young person's own account of the structure should be sought directly and weighted appropriately. And the practitioner should maintain the wider frame of Chapter 48, in which the family's structure is examined against the conditions the family lives in.

### 10.3 Ethical considerations

**Consent to family work.** A young person's consent to family sessions is required, and the structure of the sessions should be explained. A young person who is attending under protest is a young person who will be described as resistant, and the description will be believed.

**Confidentiality in a family setting.** Confidentiality cannot be absolute in a family session, and the limits should be stated at the beginning, in terms the young person can act on. The structural therapists' practice of asking the young person to keep the contents of an individual session private from the parents is ethically problematic and should be approached with care.

**The young person's right to a view.** The practitioner should not present a structural formulation to a family as an established fact. A formulation that is presented as a diagnosis will be experienced as a verdict, and the young person will be invited to accept a description of their family that they did not have a part in writing.

**The protection of the young person from the parental subsystem.** Where the work involves a challenge to a parent, the practitioner must anticipate the possibility that the parent will retaliate against the young person, and must plan for it.

**The limits of the work.** A structural intervention is an intervention in a family's organisation, and the practitioner should be clear about the limits of their mandate, about the limits of their competence, and about when the case requires a different or additional response.

**Equity of participation.** The structural model presumes that all family members can participate. The practitioner must consider the family members who cannot — a young person with a communication impairment, a parent with a learning disability, a family member who does not speak the language of the sessions — and must adapt rather than exclude.

## 11. Key Terms

**Key Terms at a Glance**

- **Family structure** — The organisation of the family, defined by its subsystems, its boundaries, and its hierarchy, and reflected in its pattern of interaction.
- **Interaction pattern** — The observable pattern of who does what to whom, as described by the family and as enacted in the consulting room.
- **Subsystem** — A group of two or more family members more closely involved with each other than with the others, with its own rules, functions, and boundaries.
- **Individual subsystem** — The person as the smallest unit of family organisation.
- **Sibling subsystem** — The group of siblings, and the unit in which the family's peer relationships are organised.
- **Parent subsystem** — The marital or spousal unit, whose relationship with the child subsystem determines much of what occurs with adolescents.
- **Discrete subsystem** — A subsystem that is clearly bounded from the others, with no crossover.
- **Nurturing subsystem** — A subsystem that is bounded in some respects and permeable in others, allowing the flow of affection and support while preserving distinctness.
- **Boundary** — The line of influence and responsibility separating the subsystems and the individuals within them; invisible but functionally decisive.
- **Diffuse boundary** — An indistinct and permeable boundary, in which the other person's thoughts, feelings, and actions are experienced as one's own.
- **Clear boundary** — A defined boundary appropriate to the developmental stage, permitting the flow of affection and support while maintaining distinctness.
- **Rigid boundary** — An impenetrable and restrictive boundary, usually the residue of a history in which closeness was experienced as dangerous.
- **Hierarchy** — The line of authority across the subsystems, in which the parents are in charge of the children.
- **Hierarchy reversal** — A parent and child who have exchanged roles, with the parent seeking direction and emotional support from the child.
- **Parentification** — A child who takes a parental function, in the practical or the emotional domain, or both.
- **Sibling inversion** — A sibling who takes a parental function over another sibling.
- **Structural map** — The standard diagram of the family, with the subsystems delineated and the boundaries and the hierarchy marked, drawn with the family in session.

**Key Terms at a Glance (continued)**

- **Enactment** — The invitation to a family to perform in the consulting room the interaction they typically perform outside it, so that the practitioner can observe the structure.
- **The interruption** — The intervention made during an enactment, in which the practitioner changes what the family is doing rather than commenting on what it has said.
- **Challenge** — The general term for the interventions by which the practitioner attempts to change the family's organisation.
- **Restructuring** — The goal of the structural interventions: the movement of a young person from the child subsystem to an adult position where the developmental stage requires it, the redrawing of the boundaries, and the restoration of the hierarchy.
- **Double bind** — Two incompatible messages given to a person with a restriction on the communication of the message, a position from which any response is a symptom.
- **Refusal of the triangulation** — The structural intervention in which the practitioner declines the role the family has assigned them and names the process.
- **Maintenance of change** — The work of keeping a restructuring in place, by securing the family's consensual and explicit commitment and by working with the parent's difficulties with the new structure.
- **Boundary renegotiation** — The developmental task of moving an adolescent from the child subsystem towards an adult position, with the accompanying changes to responsibility and participation.
- **The four structural tasks of adolescence** — Differentiation from the family of origin, the move from the child subsystem, the development of peer relationships, and the acquisition of a vocational and financial direction.
- **Two-boundary problem** — An adolescent who is closely enmeshed with one parent and rigidly distant from the other, the classic triangulated presentation.
- **Oscillating boundary** — A family that alternates between intense closeness and complete distance, so that the distance follows the closeness.
- **Enacting the sequence** — The clinical technique of asking a family member to describe a recent ordinary instance of the difficulty in detail, in order to obtain the interaction pattern.
- **Family projection process in the structural frame** — The projection of the parents' own difficulties onto a child whose structural position is shaped to receive it.

## 12. Chapter Summary

The structural model was built on the claim that the family is a structure and that the symptoms are structural in origin. Minuchin's work with families of severe and entrenched difficulty produced the claim, and the model's central intervention is a restructuring of the family's organisation, with the enactment as its signature technique.

The five key concepts were developed in turn. Structure is defined both by the subsystems, the boundaries, and the hierarchy and by the observable pattern of interaction, and the distinction between the two was emphasised because each generates a different clinical conversation. Subsystems were described with the terms discrete and nurturing. Boundaries were described in their three forms — diffuse, clear, and rigid — with the clinical presentations of each, and with the observation that the rigid boundary is usually the residue of a history in which closeness was dangerous. Hierarchy was described with its three disorders: parentification, hierarchy reversal, and sibling inversion. The family projection process was described in the specific structural sense in which the projected child is also the structurally positioned child.

Structural diagnosis was described as a four-stage procedure, and the distinction between the structural and the interactional formulation was made explicit with a worked example, because the two produce different interventions and the structural formulation is the one that predicts what will happen if the practitioner works only on the interaction.

The five principles of the model were then developed: the structure causes the symptom, the family is the unit of treatment, the intervention is the restructuring, the enactment is the means of diagnosis, and the change must be maintained. The enactment was described in detail — the procedure, what it reveals, the interruption, and the risk — with the explicit warning that the modern practice is more careful than the original about the timing of the interruption and the young person's state afterwards. The maintenance of change was described with the three requirements of consensus, explicitness, and the family's own maintenance mechanisms.

The developmental fit with adolescence was developed through the four structural tasks, and the four boundary problems were described with the intervention appropriate to each. The clinical sequence was given, and the case of the adolescent who will not attend was treated with the model's pragmatic answer, in which the refusal is read as structural information.

The case of Declan demonstrated the model in full. His symptoms were not oppositional but the report of a young person who was parentified in a family whose parental subsystem had collapsed and whose grandmother's function had been absorbed by him. The enactment produced the decisive moment — the family reorganising around a sarcastic sentence — and the practitioner's interruption asked the question that produced the formulation. The intervention was four elements, and the most important of them was the practitioner naming, in front of the young person, the family's unspoken fear that it would collapse when he stopped, and promising that it would not.

The evidence was presented honestly: the model has modest controlled evidence, and the stronger evidence in the adjacent areas is for family-based treatment of eating disorders, for behavioural family therapy, and for multisystemic therapy. The evidence's limits were named, including the serious methodological problem of the exclusion of the identified patient's own account.

The strengths and limitations were set out, and the limitations included the cultural narrowness, the risk of the model being used for enforcement, the over-confident challenge, the under-accounting of the individual, and the modest evidence. The cultural analysis examined the assumptions of the nuclear family, of the hierarchy, of the developmental path, and of the boundary metaphor itself, and the ethical section addressed consent to family work, confidentiality in the family setting, the young person's right to a view, the protection of the young person from the parental subsystem, the limits of the mandate, and the equity of participation.

# 13. Review and Discussion Questions

## Review and Discussion Questions

1. Explain the clinical problem that produced the structural model.
2. State the five key concepts of the structural model.
3. Distinguish the family structure from the interaction pattern, and give an example of each for the same family.
4. Define a subsystem, and explain the terms discrete and nurturing.
5. State the three types of boundary, describe the clinical presentation of each, and specify the intervention for each.
6. Explain hierarchy, and describe the three forms of hierarchy disorder.
7. Describe the family projection process in the structural sense.
8. State the four stages of the structural diagnostic procedure.
9. State the three uses of the structural map.
10. Produce both an interactional and a structural formulation for the same case, and explain how they point to different interventions.
11. State the five principles of structural family therapy.
12. Describe the enactment procedure, and state the four kinds of interruption.
13. Explain the risk of the enactment, and describe the modern caution about it.
14. Describe the three specific challenges: the refusal of the triangulation, the naming of the double bind, and the boundary renegotiation.
15. State the three requirements for the maintenance of change, and explain why each is necessary.
16. State the four reasons why the model fits the adolescent developmental stage.
17. State the four structural tasks of adolescence and the presentation of the failure of each.
18. Describe the two-boundary problem and the oscillating boundary.
19. State the four-session clinical sequence and the purpose of each session.
20. Describe the structural answer to the adolescent who will not attend family sessions.
21. Describe the case of Declan and state the three features of it that generalise.
22. Summarise the status of the evidence for the structural model and for the three adjacent family approaches.
23. State the four cultural assumptions of the model.
24. Explain the risk of the model's misuse as an instrument of enforcement, and the three safeguards.
25. State the six ethical requirements for structural work with young people.

## 14. Practice Activities

**Practice and Application**

### Activity 31.1 — Drawing a Structural Map (90 minutes, field-based)

In a placement, take one family and draw the structural map: the subsystems, the boundaries, and the hierarchy. Mark each boundary as clear, diffuse, or rigid, and justify each judgement from observed or reported interaction. Then write a sentence naming the position of each young person in the family. Do not share the map with the family. The exercise teaches the difference between the structure as a description and the structure as a verdict, and the third stage of the activity — the position of the young people — is where the interpretive leap has to be made.

### Activity 31.2 — The Enactment Script (75 minutes, small group)

In groups of four, one student plays a sixteen-year-old, one plays the mother, one plays the father, and one plays the practitioner. The practitioner asks the family to enact a recent instance of a conflict, and the practitioner's task is to observe and then to interrupt. The three family members then describe what happened from their own positions, and the practitioner describes what they saw. The exercise is the most instructive in the book for the enactment, because the students discover that what the family can describe and what the family can do are quite different things, and that the practitioner's intervention is a change in the behaviour rather than a comment about it.

### Activity 31.3 — The Cultural Audit of a Map (60 minutes, individual)

Take a structural map from a family in a context that is not the one in which you were trained — a different cultural setting, a different family form, a different expectation about the developmental path — and audit it. For every element of the map, ask: is this a description of this family, or is this an expectation imported from my own context? Rewrite the map so that it describes the family as it is, without the imported expectations. Most students find that a substantial part of the original map was expectation, and this is the most useful single lesson in the chapter.

### Activity 31.4 — The Refusal of the Triangulation (60 minutes, pairs, discussion)

In pairs, one student plays a parent who has been confiding in their sixteen-year-old about their marital difficulties, and the other plays the practitioner. The practitioner must refuse the role — decline to be drawn into the confidences, name the process, and explain to the parent why the arrangement is being changed. The second half of the exercise is the harder part: the practitioner must then describe what will happen next, including the fact that the parent's relationship with the practitioner may deteriorate, and including what the practitioner will do about the young person in the meantime. The preparation for this conversation is more useful than almost any other exercise in Part V.

## 15. Annotated Reading Pathways

**For the model.** Read Minuchin (1974) and then Minuchin and colleagues (1981), and read Minuchin and Nichols (1993) for the modern statement. Read the 1978 paper as the shortest complete statement of the model.

**For the technique.** Read Minuchin, Sell, and Montalvo (1998) for the clinical practice, and read the chapters on enactment and on the challenge in any current structural text. The technique is learned by supervision and by practice, and the readings support rather than substitute for it.

**For the field.** Read Nichols (2013) for the whole family therapy field, so that the structural model can be placed alongside the strategic and the Bowenian. Reading only the structural school is how a student ends up unable to compare.

**For the evidence.** Read the family-based treatment literature on adolescent eating disorders, read the behavioural family therapy evidence, and read the multisystemic therapy evidence. These are the studies that actually support the parental-involvement claim, and the structural model's central clinical assertion.

**For the critique.** Read the critique of structural family therapy on the grounds of social construction, and read the critical literature on the use of family therapy in contested and safeguarding contexts. The combination is the preparation for the work in Part VIII.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Structural Family Therapy** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is minuchin's structural model, boundaries, subsystems, and restructuring with adolescents and parents. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is family patterns, attachment, boundaries, communication, stories, and relational resources. The mechanism to keep in view is how interaction sequences and shared meanings distribute distress, protection, responsibility, and possibility across a system. The characteristic professional risk is blaming families, exposing a young person in unsafe joint sessions, or ignoring material conditions and individual needs. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in family meetings, school consultations, care networks, and individual sessions informed by systems thinking, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning,

language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Nia is fifteen and is seen in a school counselling service for shame after academic failure. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Nia's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Nia explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on family patterns, attachment, boundaries, communication, stories, and relational resources. The first intervention is deliberately modest. Nia chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what

will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Nia has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Nia can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.

- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Structural Family Therapy

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Structural Family Therapy** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

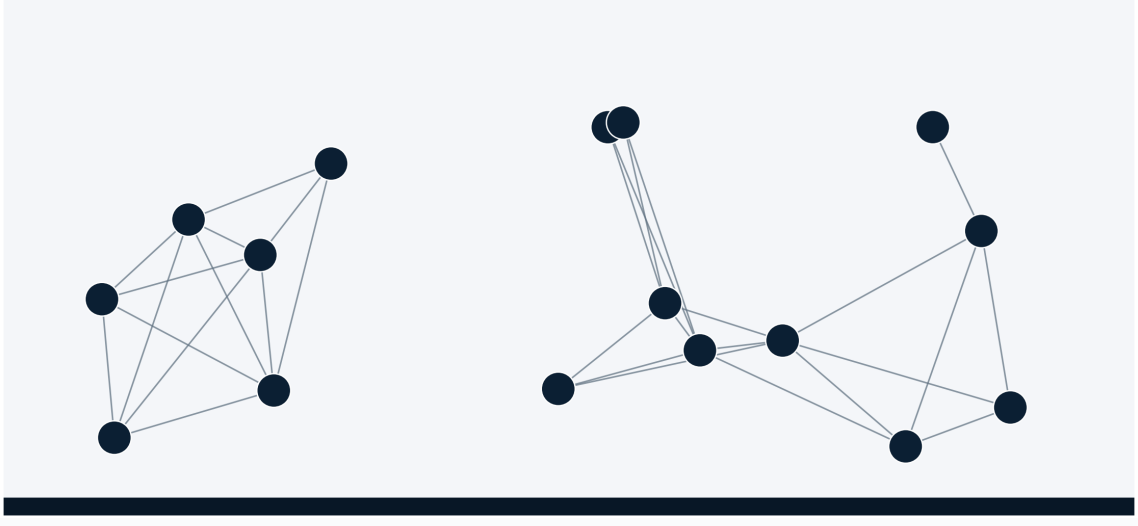
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Structural Family Therapy** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a

professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Structural Family Therapy**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Structural Family Therapy to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 32

# Strategic Family Therapy and Communication Theory

Problem-maintaining sequences, directives, and the reframing of the problem.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the development of the strategic school and describe the clinical problems that produced it.
- State the core concepts of the strategic model, including the problem-maintaining sequence, the double bind, the symptom as a metaphor, and the reframing.
- Describe the techniques of the strategic school: the enactment of the sequence, the directives, the prescription, the reframe, and the restriction.
- Explain the contribution of communication theory to the field, and distinguish it from the strategic model.
- Describe the "team of the strategic" approach and the concept of the problem as a solution.
- Apply the strategic framework to a case involving an adolescent and a family.
- Critically evaluate the ethical and cultural dimensions of strategic family work, particularly the use of directives and the question of deception.

## Chapter Overview

The strategic school began as an answer to a question the structural therapists had not asked. If a symptom is structural in origin, then the structure is the treatment target. But Jay Haley and his colleagues in the Mental Research Institute in Palo Alto asked a different question: **what maintains the problem right now?**

Their answer was that a problem continues because it solves something. The young person who refuses to go to school, who is unable to say no, or who has become quiet and withdrawn, is doing something that has consequences the young person needs, and the symptom will not go away while the consequences continue. The strategic therapist's task is therefore to identify the sequence in which the problem is produced and maintained, to change the sequence, and to use the young person's own motivation for change rather than a confrontation.

The strategic school's technical repertoire is distinctive and it is worth knowing it in detail, because some of it is directly transferable to other modalities and some of it is ethically hazardous in ways that the profession has had to confront.

**The problem-maintaining sequence** is the central clinical object. It is the specific chain of events, from the trigger through the young person's behaviour to the family's response and back, that keeps the problem going. It is mapped in detail, and it is mapped in the family's own terms.

**The directive** is a specific, dated, behavioural instruction given by the therapist to a family member. It is the strategic school's most distinctive intervention and the one with the most interesting ethical profile.

**The prescription** is a task that is deliberately difficult, designed to fail in a way that produces a new and more adaptive response.

**The reframing** is the reinterpretation of the problem, offered to the family in a way that makes the symptom more understandable and more tolerable, and that implicitly suggests a way out.

**The restriction** is the instruction to suspend a behaviour that has become a trap, most commonly a parental response that has inadvertently become the solution to the problem.

**Communication theory** — the study of the patterned exchanges between people, and the observation that a communication is always about something and is always a response to a communication — sits alongside the strategic model in the same tradition and supplies the analytic vocabulary. The most famous contribution is the description of the **double bind**, and the observation that a family in which every communication is a metacommunication — a comment about a comment — has a very serious problem.

This chapter presents the model, the communication theory that underlies it, the techniques, and the ethical analysis, which in this school is unusually substantial because the school's techniques include the deliberate management of information.

# 1. Historical Context

## 1.1 The Mental Research Institute

The strategic school developed in the 1960s at the Mental Research Institute in Palo Alto, California, in a project on the communication of families with a member who had been diagnosed as schizophrenic. The project was led by Gregory Bateson, with Don Jackson, Paul Watzlawick, and John Weakland, and it produced the work that is now called communication theory.

The founding observation was that the families of people diagnosed with schizophrenia communicated in distinctive ways, and the distinctive feature was not the content of the communications but their patterning. The families were characterised by **double binds** — in which a person receives two incompatible messages with a restriction on the communication of the message — and by **symmetrical and complementary** patterns of interaction, and by a communication system in which every message was a comment on a previous message, so that no message could be checked against reality.

The clinical significance of the finding was modest — the double bind did not explain schizophrenia, and the field has long since rejected the attempt to explain it — but the analytic contribution was enormous, and the vocabulary it produced is now the shared language of all the family therapies.

## 1.2 Haley and the strategic school

Jay Haley moved from the research group into the clinical work and developed the strategic model, and the shift is worth tracing because it explains the character of the model.

In the research setting, the goal was to describe. In the clinical setting, the goal is to change, and a description is valuable only insofar as it points to a change. Haley's contribution was to take the communication analysis and turn it into a set of **directives** — specific instructions, given by the therapist, that interrupt the sequence and produce a different outcome.

**Haley's "tricks"** — the paradoxical injunction, the paradoxical prescription, the ordeal, the team of the strategic — were his characteristic innovations, and they are technically brilliant and ethically contested, and the contemporary field has retained some of them and abandoned others.

## 1.3 The problem of the stuck family

The clinical problem the school addressed was the **stuck family**: the family in which the problem has been stable for a long time, in which everyone knows the pattern, in which previous attempts at change have produced more of the same, and in which the family has come to see the problem as the price of the family.

The strategic school's answer was to change the meaning of the problem before changing the behaviour. If the young person's symptom is understood as the solution to a problem the family cannot solve any other way, then the symptom will not go away until the family can solve the problem some other way. The reframing supplies that other way, and the directive tests it.

### 1.4 The place of the strategic school today

The strategic model's influence on the field is very large and diffuse. The **solution-focused** work of Chapter 35, the **narrative** work of Chapter 36, and the **communication-based** approaches to eating disorders and to substance use all descend in part from it. The concept of the **"problem is a solution"** has entered the general vocabulary of family therapy. The model's technical vocabulary of sequences, directives, and reframings is standard in the training of every family therapist.

The model's specific techniques, however, have been substantially modified, and the two most controversial — the paradoxical injunction and the deliberate management of information — are now used far more cautiously.

## 2. The Core Concepts

### 2.1 The problem-maintaining sequence

The **problem-maintaining sequence** is the central clinical object of the model. It is a specific, mapped, and dated chain of events that keeps the problem going, and it is mapped in a form that makes each element a candidate for change.

A typical sequence in a school-refusal case runs like this: the young person is asked to go to school → the young person says she is ill → the parent believes her → the parent contacts the school → the parent tells the school the child is ill → the school agrees → the young person stays at home → the day passes → the young person is at home again without having had to face the school → the next morning is another day on which the sequence can begin.

Every element is a candidate for change, and the mapping makes the clinical possibilities visible. A change at the "the parent believes her" point produces a different outcome. A change at the "the school agrees" point produces a different outcome. A change at the "the day passes" point — that is, an activity that makes the day at home less tolerable — produces a different outcome.

The mapping is done **in the family's own words** and with **specific instances**, and the practitioner should be able to state the general rule and the specific example. A generic sequence is useless.

### 2.2 The symptom as a solution

The strategic school's foundational claim is that **the symptom is a solution**. The young person's behaviour is not the problem; it is the best solution the family has found to a problem that is not being solved any other way.

The claim has three parts. The problem is a **dilemma** — it is a genuine problem and a solution at the same time, and the two cannot be separated. The solution has **side effects** that are the reason for referral. And the solution is **not the only one**, which is the space in which the therapy operates.

The reformulation of the referral is then something like: "the current solution to the problem of X is Y, and Y is now causing more difficulty than it was designed to solve, and there is another solution available."

## 2.3 The double bind

The **double bind** is the communication pattern in which a person receives two mutually incompatible messages, and is unable to comment on, question, or escape the situation in which they receive them. Bateson's formulation has four conditions, and a student should be able to state them.

1. There must be a **contradictory pair of messages**.
2. There must be a **repeated pattern** in which the contradiction is maintained.
3. There must be a **restriction on the recipient's ability to respond** — to question, to comment, to leave.
4. There must be a **punishment or a threat** for any attempt to resolve the contradiction by noticing it.

In practice, the double bind is rarely a matter of two spoken messages. It is more often a mismatch between what is said and what is done: a parent says "you are an adult, make your own decisions" while punishing any decision that differs from the parent's own. The young person is thereby unable to act, unable to refuse, and unable to name what is happening, and the inability to name it is a substantial part of why the pattern persists.

**Bateson's paradox.** A self-referential paradox occurs when the message denies the validity of the communication system in which it is transmitted, and a young person who is told "don't question me" and "you should question me" is caught in it. The clinical significance of the concept for the practitioner is that the young person is in a position in which the most reasonable responses are all pathological: compliance produces resentment, resistance produces punishment, and the attempt to discuss it is itself treated as an offense.

## 2.4 Symmetrical and complementary patterns

**Symmetrical** patterns are those in which the participants' behaviours mirror each other: the escalating and escalating, the withdrawing and withdrawing, the panic and the panic. Symmetrical interactions tend to escalate and to be difficult to interrupt.

**Complementary** patterns are those in which the participants' behaviours are complementary to each other: the one is dominant and the other is submissive, the one is anxious and the other is reassuring. Complementary interactions are stable and can be highly functional, and they are also the patterns in which a problem is most easily maintained, because the roles are mutually reinforcing: the more the one withdraws, the more the other pursues, and the more the other pursues, the more the first withdraws.

## 2.5 The metacommunication

A **metacommunication** is a communication about a communication. Every message carries, in addition to its content, a commentary on the relationship in which it is transmitted: *I am telling you what to do*, *I am asking you*, *I am warning you*, *I am apologising*.

A family in which every message is a metacommunication has a serious problem, because the content becomes unavailable for checking against reality. The young person who is told "I am just telling you for your own good" is receiving a message that cannot be examined, because examining it would be a comment

on the metacommunication, which is the prohibited move.

The clinical task in work with such a family is to **restore the ability to make content statements** — to get the family to a place where a message can be said to be true or false — and this is often the first substantive change in the work.

# 3. The Techniques

## 3.1 The enactment of the sequence

As in the structural model, the sequence is enacted in the consulting room, but the purpose differs. The structural enactment is diagnostic of the *structure*; the strategic enactment is a **test** of the sequence, and the intervention is made at the point at which the sequence is about to complete itself.

The technique is delicate. The practitioner interrupts at the moment at which the young person is about to say the thing that will produce the family response, and says something that stops the sequence — a question, a request for information, a statement that the practitioner has noticed something. The interruption demonstrates that the sequence is not inevitable, and the demonstration is the intervention.

## 3.2 The directive

A **directive** is a specific, dated, behavioural instruction given by the therapist to a family member. It is the strategic school's most distinctive intervention, and its distinguishing features are its specificity, its attribution to the therapist, and its date.

**The attribution matters.** A directive is not a suggestion and not a request. The therapist says, "I am telling you to do this, and I am telling you because I am the person in this room with the most experience of this problem." The attribution provides the authority that the instruction requires, and the strategic therapists were clear that a directive issued as advice is a wasted instruction.

**The specificity matters.** A directive must be concrete enough to be performed: not "be firmer with him" but "when he asks to go up to his room, you will say 'you may go up to your room for ten minutes after you have done the washing-up, and I will knock on your door at seven'."

**The date matters.** A directive with no date is a wish.

**The directive must produce a testable result.** The strategic school's directives are designed so that something happens that either confirms or disconfirms the hypothesis, and the test is what keeps the work from becoming manipulation.

## 3.3 The paradoxical injunction

The **paradoxical injunction** is a directive that asks a family member to do the very thing the symptom involves, and to do it deliberately, and at a time and in a manner that makes it tolerable or even useful.

The reasoning is that the symptom is maintained by the family's attempt to prevent it. If the young person's withdrawal is met with escalating attempts to prevent it, the withdrawal continues. If the withdrawal is permitted, and even encouraged, in a way that is clearly deliberate, the meaning changes: the young person is no longer doing it to defy, and the family is no longer trying to prevent it, and the sequence that maintained it is broken.

The paradoxical injunction is the most technically elegant and the most ethically hazardous intervention in the family therapy field, and the ethical analysis in Section 10 is devoted to it.

## 3.4 The paradoxical prescription

The **paradoxical prescription** asks a family member to perform the symptom's function deliberately, in a way that will probably fail, in order that the failure will be instructive. If a young person is refusing to go to school, the paradoxical prescription might be: "I want you to make sure she does not go to school. I want you to be the one who keeps her at home. I want you to take over, completely, for the next two weeks."

The mechanism is that the prescription is impossible to perform, and the impossibility exposes the family to the fact that the solution they have been relying on does not work, and the exposure is what makes a different solution available. The technique is used in the treatment of problems that are maintained by a paradoxical pattern, and it is a sophisticated intervention with a small place in contemporary practice.

## 3.5 The ordeal

The **ordeal** asks a family member to undertake a difficult task with a defined and serious cost, undertaken after and for the sake of a change in the identified patient. The reasoning is that a task that is costly enough will mobilise a commitment that no instruction can.

The technique is now almost entirely discredited, and it should be understood historically. Its clinical rationale was that the ordeal demonstrated that the family would pay a real price for the change, and that this demonstration changed the family members' positions. Its ethical problems are severe: the burden falls on a family member who did not choose the symptom, the "cost" is real suffering, and the pressure on a vulnerable family member is difficult to distinguish from coercion.

## 3.6 The reframing

The **reframe** is the reinterpretation of the problem, and it is the most useful of the strategic interventions in contemporary practice, because it is also the least hazardous.

A reframe offers the family a different account of the symptom that makes it more understandable, more tolerable, and more tractable. It must be offered as a *hypothesis*, and it must fit the facts, and it must be a reframe that the family can use.

Some of the strategic school's reframes are famous and some are now regarded as objectionable. The reframe of the "identified patient" as the family's **sacrificial scapegoat** was central to the school's theory and is now understood as historically important and currently unacceptable, because it attributes a family member's illness to the family's need, and it can be heard as a claim that the young person is faking, which is both untrue and damaging.

A more defensible reframe in contemporary use: the young person who cannot leave the house is not refusing to leave but is unable to manage the state that leaving produces; the young person who cannot say no is not being difficult but is doing the only thing available in a system where saying yes has never been safe; the young person who cannot concentrate is not being lazy but is protecting herself from a level of stimulation that is intolerable.

The clinical test of a reframe is whether it opens a door or closes one. A reframe that the family hears as an accusation closes the door. A reframe that the family hears as a relief opens it.

### 3.7 The restriction

A **restriction** is an instruction to suspend a behaviour that has become part of the problem. The classic example is a parent whose vigilance has become the very stimulus the young person reacts to: a mother who checks on her daughter every twenty minutes, whose concern has trained the daughter to become alert at the sound of the door.

The restriction is straightforward to make and surprisingly powerful, and it is one of the interventions that most reliably produces a change in the sequence, because the sequence depends on the behaviour being restricted.

### 3.8 The team of the strategic

The **team of the strategic** is a technique in which a family member is instructed to become the therapist's ally in changing another family member, and to do so covertly. The father is instructed to cooperate with the mother's new plan while appearing to the mother to be the ally of the family against the practitioner.

The technique is powerful and it is ethically the most contentious in the family therapy field, because it involves the deliberate management of information in a way that the person being managed is not aware of. The ethical analysis in Section 10 addresses it directly, and the contemporary position is that the technique should be used only with the explicit knowledge of all parties and with the informed consent of the person whose information is being managed.

## 4. Communication Theory in Practice

### 4.1 The rules of communication

Communication theory's contribution to practice is a set of observations about the rules that govern family interaction, and the four most useful are as follows.

**You cannot not communicate.** Every behaviour, including the refusal to speak, is a message. This has a direct clinical consequence: the practitioner should not treat a young person's silence as an absence of communication but as a communication, and should ask what the silence is doing.

**Everything has a meaning. You cannot not have a meaning.** Every message implies a claim about the relationship and about the legitimate range of what may be said. The claim implied by "you should know better than to ask" is that the ask was illegitimate, and the recipient learns this.

**You cannot get a message other than the one you send. Communication is irreversible. And you cannot not understand a message. Once you have understood a message, you cannot forget it.** The clinical consequence is that the practitioner's own messages to a family are irreversible, and that a practitioner's poorly worded remark in a corridor will be understood and will not be forgotten.

**Communication is always contextual. Every message has a metacommunication, and every metacommunication is a comment on the previous message.** A family locked into a metacommunicative spiral has lost the ability to make content statements, and the first task is to restore it.

### 4.2 The double bind with adolescents

The double bind is particularly relevant to adolescents, and three common forms recur.

**The developmental double bind.** The parent requires the adolescent to be a child in the areas of dependence and an adult in the areas of responsibility. The adolescent cannot win: the child behaviour is punished as immature and the adult behaviour is punished as insolence.

**The love–control bind.** "I do this because I love you" combined with "you are not allowed to have a say in this" is a double bind in which the message of care is used to prevent the very response that would make the care effective.

**The two-message bind.** The verbal message and the non-verbal message contradict each other: the parent says "of course you can go out" while the facial expression, the sigh, and the tone say the opposite. The adolescent is caught, and the double bind is reinforced when the adolescent mentions it, because the parental response to the mention is a defence of the parent.

### 4.3 The communication audit

A practical technique from the communication tradition is the **communication audit**: the family member is asked to record, over a defined period, the messages they receive and send, and the practitioner and the family member then examine them together.

For an adolescent, a simplified version is often productive: the young person is asked to record the messages they receive about school, about curfews, about friends, and about their body, and to note the content and the metacommunication, and the two then look for the contradictions. The exercise is also a useful anxiety-management technique, since the recording converts a diffuse sense of being controlled into a specific set of statements that can be examined.

## 5. Further Reading for This Chapter

- Bateson, G., Jackson, D. D., Haley, J., & Weakland, J. (1964). *Toward a theory of schizophrenia*. — The primary source for communication theory and the double bind.
- Watzlawick, P., Beavin, J. H., & Jackson, S. D. (1967). *Pragmatics of human communication*. — The formulation of the rules.
- Haley, J. (1963). *Strategies of psychotherapy*. — The strategic school's founding clinical text.
- Haley, J. (1976). *Problem-solving therapy*. — The mature statement.
- Haley, J. (1984). *Ordeal therapy*. — The controversial techniques, described by their author.
- Madanes, C. (1981). *Strategic family therapy*. — The clearest textbook exposition.

- de Shazer, S. (1985). *Keys to solution in brief therapy*. — The intellectual origin of the solution-focused school.
- Rackson, A. (2006). *Strategic family therapy*. — The modern clinical text.
- Andolfi, J., & Canestri, A. (2008). *The new school of family therapy*. — The Milan tradition, which is strategic in its core.
- Cecchin, G., Prata, S. E., et al. (2012). *Systemic family therapy with adolescents*. — The contemporary application.

- Jackson, S. D. (1992). *Using feedback to change behaviour*. — The theory of the double bind developed.
- Satir, V., et al. (1988). *The new peoplemaking*. — Satir's model, which sits alongside the strategic work.
- Risley, B. (2016). *Communication and the family system*. — The practical communication work.

# 6. Strategic Work with Children and Adolescents

## 6.1 The fit

The strategic model fits the adolescent work of this book for reasons that are partly clinical and partly opportunistic.

**It takes the symptom seriously as a solution.** The adolescent's symptom has a function, and the model does not treat the function as a rationalisation. This is congenial with the adolescent's developmental reality: a young person who is failing to attend school, who cannot say no, or who has stopped speaking is usually doing something that has worked.

**It uses the young person's own motivation.** The strategic school's first question is what the young person wants. The "problem is a solution" formulation means that the young person has a goal, and the goal is legitimate, and the work is directed at finding a route to it that does not require the symptom. This is an unusually respectful starting point and it fits the developmental task of establishing an autonomous position.

**It is fast and it is directive.** Strategic work with an adolescent is often brief, and it is often more effective with adolescents than exploratory work, because the directiveness of the approach is experienced as respect rather than as intrusion. Many young people who are wary of therapy respond better to a practitioner who says "I am going to tell you what to do this week" than to one who asks open questions.

**It maps something that can be changed.** The problem-maintaining sequence is a description of the present, and the present is the only thing on which the intervention can act.

## 6.2 The specific adaptations

**Sequence the complaints.** Before the first family session, ask the young person to list, in order, the things they would like to be different, and ask which is the most annoying. A young person who is consulted about the order of the agenda will engage with the agenda; a young person who is presented with a list of the adults' priorities will not.

**Find the "if you were me" moment.** A strategic technique for young people is to ask what the young person would do if they were the parent, and what they would say, and then to explore what would have to be true for that to work. The exercise is engaging, it is often revealing, and it places the young person in the position of an expert, which is developmentally appropriate and is markedly different from the position in which most referrals place them.

**Use the sequence with the school.** The problem-maintaining sequence for a school refusal usually runs through the school as much as through the family, and the intervention at the "the school agrees" point is often the one that matters most, and it requires the practitioner to work with the school, which is consultation work and is described in Chapter 56.

**Watch the paradoxical move carefully with adolescents.** The paradoxical injunction is the technique most likely to be misunderstood by an adolescent and most likely to be misread by a parent, and the current

practice is to use the technique only where the young person is present, is told what is happening and why, and has agreed to it in advance. The ethical analysis in Section 10 sets this out in full.

**Use the restriction early.** Restrictions are easy to make, produce observable effects quickly, and give the family a first experience of the sequence changing, which is what makes the rest of the work possible.

### 6.3 The problem with the symptom-as-solution formulation

The formulation has a real risk that a student should be able to name: **the risk that the young person's symptom is read as a manoeuvre.** If the practitioner believes that the young person is maintaining the symptom deliberately, the whole frame becomes an accusation, and the family will hear it as one, and the young person will be confirmed in their belief that the adults are trying to catch them out.

The discipline required is to hold the formulation at the level of the **system** rather than the level of the individual. The question is not "is the young person doing this on purpose?" but "what happens in this family, in response to this behaviour, that makes the behaviour the best available option?" The first question is a question about a person's sincerity, which is usually unanswerable and always unhelpful. The second is a question about a system, which is answerable and is what the practitioner can change.

### 6.4 The reformulation of the referral

A distinctive and useful feature of the strategic model is the **reformulation of the referral**, and a student should be able to perform it. The procedure has four steps.

**Take the referral literally.** What exactly has been asked for, by whom, and in what words?

**Ask what the family is currently doing about it.** The family's own efforts are the most informative data available, and the pattern of what they do and do not do is the sequence.

**Find what the symptom is doing for the young person.** What does it accomplish? What does it prevent? What does it permit?

**Offer an alternative.** The strategic school's formulation ends in a different solution, and the formulation is incomplete until the alternative is named.

A worked example. Referral: "a fourteen-year-old boy who refuses to speak to his mother and is being oppositional." Strategic reformulation: "When he refuses to speak, his mother stops asking and his father steps in and the two of them argue while he is upstairs, and he is not spoken to for the rest of the evening, and the following morning the pattern is that the mother is formal and the father is the one who talks to him about football. The silence is doing three things: it stops the arguments, it preserves his position as the one who has a private channel with his father, and it keeps his mother at a distance that he is not yet able to manage. The alternative we are looking for is a way for him to be left alone without the silence having to be the instrument."

## 7. Case Illustration: The Young Woman Who Was Refusing to Grow Up

**Presentation.** Iris is seventeen, in her final year at a sixth-form college, and has been referred by her mother with a message that the college has passed on: "She has decided she is going to work in a shop and she's not going to get her grades, and she won't listen to reason." The mother's stated worry is that Iris is "throwing

her life away" and that the family is going to lose the money that the college has cost.

**The individual session.** Iris's own account is consistent and calm and does not match the referral at all. She says that she has decided to work in a shop because her mother has been talking about "the money" every day for six weeks, and that the message she has received is that the family cannot afford the college and that she is expected to sacrifice. She says that she has done the calculations and that she would rather work and be independent than stay and be a burden. She says she is not angry with her mother. She says she has already applied for two jobs.

She also says the thing that changes the case: "If I got the grades, I'd have to go to university, and then I'd be at home for another three years doing a subject I don't want, and I'd have to leave again. Staying at home and working is the only way I can see of getting out of here for good."

**The sequence.** The practitioner maps the sequence, and the mapping is done with Iris, in the session, and it is the most important part of the assessment.

The sequence runs: Iris mentions a possible job → her mother becomes anxious and the conversation turns to money → the mother says something about the cost of the college and about how the family is managing → Iris's face closes → Iris stops responding → the mother raises her voice and cites the money again → Iris leaves the room → the mother interprets the leaving as the proof that Iris does not care → the mother mentions it to Iris's aunt, and to the college, and to Iris's father, who is absent from the house and is contacted by telephone → Iris hears, from her aunt, that her mother has "given up" on her → Iris confirms to herself that she is a burden and that leaving is the only option that is not a burden.

The sequence has a specific and important feature: **the money is not actually the problem.** The mother's anxiety about money is real and is a genuine constraint, and the money is the vehicle on which the anxiety is expressed, and the escalation it produces is what Iris experiences as being told to sacrifice.

**The reformulation.** The strategic reformulation is: *Iris is not refusing to grow up. Iris has found a solution to a problem that the family has not been able to name, which is that the family has no route by which Iris can leave. The current solution is to leave by dropping out, which delivers her independence at the price of her future options. The alternative is to find a route by which she can leave with her future intact, and to do it in a way that does not require her mother to be told that she is the reason Iris is leaving.*

**The intervention.** Three elements.

*Element one: the mother, alone.* The practitioner sees the mother on her own, and the conversation is about the money, and the practitioner is careful: the money is real, the family's financial situation is what it is, and the college costs what it costs, and none of that is disputed. What the practitioner then works on is the *timing* of the money conversation. It occurs every day, it occurs in relation to Iris, and it occurs in a form that is a complaint. The practitioner asks the mother what she would like to happen with the money, and the mother says she wants Iris to finish the year, and the practitioner asks what she wants to happen if Iris does not, and the mother says "I don't know" and then says, after a pause, "I suppose I'd have to find a way." The practitioner returns to this every session: the money is solvable, and the money is not the real issue.

*Element two: the reframe.* The practitioner offers a reframe to the mother, and it is offered as a hypothesis and it is the sentence that changes the case: "I think Iris is not refusing to grow up. I think she is trying to leave, and the only route she can see is the one that costs you the most. And I think she has worked out that if she leaves with the grades, she will have to leave anyway, and be back."

The mother says: "She never said that." The practitioner says: "No. But she has been working it out for months, and she has been doing the arithmetic at two in the morning rather than at the kitchen table, and I think it would help if we brought it out."

*Element three: the directive.* The strategic school's directive is what makes the reframe operational, and it is specific and dated and given with attribution. The practitioner tells the mother: "For the next two weeks, you are not going to talk to Iris about money. Not once. If she raises it, you will say, 'We are going to talk about this with Ms Adeyemi on Thursday, and until then I am not discussing it.' You will not raise it, and you will not hint at it, and you will not ask her whether she has thought about the money. I am telling you to do this because I am the person in this room who has the most experience of this particular problem, and I am telling you because it is the only way we will find out whether the money is the problem."

**The outcome.** On the Thursday, Iris says almost exactly what the practitioner predicted: she does not want to work in a shop, she is frightened that the family will not be able to pay for a university, and she does not know how to say that without it sounding like an accusation. The financial plan is then made with the mother's help and with the college's financial support office, which has funds that nobody had asked about, and the practical problem — which was real — turns out to be solvable.

Iris completes the year with three A-levels and applies to university. The relationship between her and her mother is not warm; it is functional, and the practitioner regards that as the realistic outcome and says so to both of them.

**The interpretation.** The case illustrates the strategic model completely. The symptom was a solution; the sequence was mapped in the family's own words; the reframe was specific and was offered as a hypothesis; the directive was specific, dated, attributed, and designed to produce a testable result. And the most important clinical move was the refusal to accept the referral's framing — the practitioner did not treat Iris as a problem and her mother as an adult with legitimate concerns, and treated the referral itself as a symptom of the family system.

# 8. Evidence and Research Support

## 8.1 The status of the evidence

The strategic school has a modest and difficult evidence base, and the reasons are instructive.

**There is little controlled outcome research on the strategic model as a whole.** The school emerged from a research group that was interested in the description of communication rather than in the evaluation of treatment, and the tradition has been more clinical than experimental.

**The research that does exist on the strategic school's specific techniques is largely negative or inconclusive.** The studies of the paradoxical injunction and the paradoxical prescription have not produced support for the techniques as general interventions, and the ethical concerns have reduced their use considerably.

**The evidence for family-based and systemic approaches that are strategic in their core is good.** The family-based treatment of adolescent eating disorders, the behavioural family therapy approaches, and the community-based systemic interventions all share the strategic premise that the problem is maintained by a sequence and that changing the sequence changes the problem. This is the most useful way for a student to think about the evidence: the strategic model is best understood not as a distinct intervention with its own

evidence but as a way of thinking that is embedded in a good deal of the effective family-based work.

**The solution-focused work that grew from the strategic school has become the best-evidenced of the family-derived approaches**, and Chapter 35 develops it. The solution-focused approaches are the strategic school's most successful and most ethical descendant, and the reason is instructive: the solution-focused work took the strategic school's insight about sequence and reframing and removed the elements that were hazardous, retaining the reframe, the directive, and the emphasis on the future.

### 8.2 Limitations of the evidence

**The allegiance effects are very large** in the family literature generally and in the strategic school in particular, and the field's own reviews have been unusually candid about this.

**The outcomes are proximal** and the distal outcomes are rarely measured.

**The "problems as solutions" framing is difficult to evaluate**, because a formulation that explains the symptom as functional is in some respects unfalsifiable, and a student who adopts the model uncritically may find that every outcome can be explained as the problem continuing to serve its function.

**The evidence base for the techniques has not caught up with their use**, and the field has had to rely on clinical judgement and ethical argument for the assessment of the more controversial interventions.

## 9. Strengths and Limitations of the Strategic Model

### 9.1 Strengths

**It takes the symptom seriously.** The reframing of the referral is a humane and clinically productive act.

**It identifies what is changeable.** The problem-maintaining sequence is a description of the present, and the present is where the leverage is.

**It uses the young person's motivation rather than fighting it.** The strategic model's respect for the young person's own goal is a genuine clinical asset.

**It is fast.** Strategic work with adolescents is often brief, and brevity is a clinical advantage with a population that does not stay.

**It is directive, and some young people need that.** The model's willingness to instruct rather than to explore is a feature with a population that experiences exploratory therapy as evasive.

**It produces testable interventions.** A directive is designed to produce a result that confirms or disconfirms the hypothesis, which keeps the work honest.

### 9.2 Limitations

**The symptom-as-solution formulation can become an accusation.** The risk is real and it has damaged young people in real cases.

**The technical repertoire contains interventions that are ethically indefensible in their original form**, and the ordeals in particular should be understood as history.

**It is a model of the family as a system of messages, and it under-accounts for what the family members actually feel.** A family that is a system of communication is a family that is not in pain, and the

model has no very good answer to the young person who is in pain.

**The evidence is thin**, and the field has been more successful in the successor schools than in the school itself.

**It under-accounts for the structural and the material.** A young person who cannot attend school because the school is unsafe, or because the family has no transport, is not maintaining a solution.

**The techniques are easy to deploy badly.** A directive issued without the skill to design it is a manipulation, and a reframe that does not fit is a lie.

# 10. Cultural and Ethical Considerations

## 10.1 The ethics of directive work

The directive is the technique in this chapter that most requires ethical care, and the principles are worth stating precisely.

**A directive is an exercise of professional authority and must be given as one.** The strategic therapists insisted that a directive be attributed to the therapist and not disguised as a suggestion, and this is ethically correct: a disguised directive is manipulation, and the young person is entitled to know that an adult with authority is telling them what to do.

**A directive must be for the young person's benefit or be one they have agreed to.** The strategic school's controversial directives have typically been in the young person's interest in the model's terms, and the question "in whose interest" is precisely what the ethical analysis must examine rather than assume.

**A directive must be safe.** The ordeals were not. Any contemporary directive must be satisfiable, must not expose the young person to risk, and must not require a family member to suffer.

**A directive must be transparent in its purpose.** The young person should know, as far as is possible, what the directive is designed to change and what it is designed to test.

## 10.2 The ethics of the team of the strategic

The team of the strategic — instructing one family member to covertly act as the therapist's ally — is the technique in this book that most directly confronts the principle of informed consent, and the contemporary professional position is clear.

The technique involves deliberately managing information about a person's own behaviour in a way that the person does not know. In family work, where the family's confidentiality is already a negotiated and partial thing, the practice of adding a covert layer has been widely criticised, and the criticism is well founded.

Three requirements follow for any contemporary use. The person whose information is being managed must be informed of what is being done and must have the opportunity to object. The people who are being asked to act as allies must understand exactly what they are being asked to do, including the fact that they will be concealing it. And the person who is the object of the intervention must be able to end the arrangement.

A student who is asked to deploy the team of the strategic without these safeguards should treat the request as a request for training and supervision, and should not comply without them.

## 10.3 The ethics of deception and reframing

The **reframe** is generally defensible, and it is important to distinguish it from deception. A reframe offers a different account that is *true*, or at least more nearly true than the account in place, and that makes the problem more understandable. A deception offers an account that the practitioner does not believe.

The test is simple and the practitioner should be able to state it: **is the practitioner willing for the young person to know how the practitioner arrived at this formulation?** If the answer is no, it is a deception, and the practice is not defensible.

The second test is whether the reframe serves the young person or the adults. A reframe that enables the parents to be more comfortable while the young person remains in the same bind is a reframe in the service of the adults.

### 10.4 Cultural considerations

**Communication styles vary.** Directness, indirectness, the use of silence, the degree of explicitness in disagreement, and the conventions of respect all vary across cultures and across families, and a practitioner who reads a family as double-bound may be reading a culture as double-bound.

**Hierarchy and the strategic directive.** The strategic model's directives are issued by the professional to the family, and in a context in which the professional's standing is not established, or in which the family's internal hierarchy is the real authority, a directive may be ignored or may cause offence, and the practitioner should understand the refusal as information.

**The family as a unit.** The strategic model assumes that the family is the meaningful unit of the problem. Where the young person's primary attachment is to a kinship network, a peer group, a religious community, or a cultural group that the practitioner does not see, the model will miss the actual system.

**Language and the metacommunication.** The analysis of communication is unusually sensitive to language, and a practitioner working across languages will find that the metacommunication is in a language the young person does not share, or that the family code-switches in ways that conceal the pattern from a non-fluent observer. The practitioner should involve an interpreter and should treat the interpreter as a clinical colleague rather than as a logistics function.

**The economic framing.** The strategic model's willingness to say that the money is not the real problem is a luxury in a setting in which the money is the real problem, and the practitioner must establish the material facts before offering the reframe.

## 11. Key Terms

**Key Terms at a Glance**

- **Strategic family therapy** — The school developed from the Mental Research Institute in Palo Alto, in which the family is understood as a system of communication and the clinician intervenes by changing the sequences that maintain the problem.
- **Problem-maintaining sequence** — The specific, mapped, and dated chain of events that keeps the problem going, and the central clinical object of the model.
- **Symptom as a solution** — The claim that the symptom is the best available solution to a problem the family cannot otherwise solve, and that its side effects are the reason for referral.
- **Problem as a dilemma** — The formulation in which the problem is simultaneously a genuine problem and a solution, and the two cannot be separated.
- **Directive** — A specific, dated, behavioural instruction given by the therapist to a family member, attributed to the therapist, and designed to produce a testable result.
- **The attributes of a directive** — Specificity, attribution to the therapist, and a date; a directive issued as advice is a wasted instruction.
- **Paradoxical injunction** — A directive asking a family member to do deliberately what the symptom involves, so that the meaning of the behaviour changes and the maintaining sequence is broken.
- **Paradoxical prescription** — A task that is deliberately difficult and probably impossible, whose failure exposes the family to the inadequacy of its current solution.
- **Ordeal** — A task of serious cost undertaken for the sake of a change in the identified patient; now almost entirely discredited.
- **Reframe** — The reinterpretation of the problem, offered as a hypothesis, that makes the symptom more understandable and more tractable.
- **The test of a reframe** — Whether the practitioner would be willing for the young person to know how the formulation was reached, and whether the reframe serves the young person or the adults.
- **Restriction** — An instruction to suspend a family member's behaviour that has become part of the maintaining sequence.
- **Team of the strategic** — The technique in which a family member is instructed to act as the therapist's covert ally in changing another family member.
- **Communication theory** — The analysis of the patterned exchanges between people, developed by Bateson and colleagues and supplying the vocabulary of the family therapy field.
- **Double bind** — Two incompatible messages received under a restriction on the recipient's ability to respond, and a punishment for attempting to resolve the contradiction by noticing it.

**Key Terms at a Glance (continued)**

- **The four conditions of a double bind** — A contradictory pair of messages, a repeated pattern, a restriction on the response, and a punishment for attempting to resolve the contradiction.
- **Bateson's paradox** — A self-referential contradiction in which the message denies the validity of the communication system in which it is transmitted.
- **Symmetrical interaction** — A pattern in which the participants' behaviours mirror each other, tending to escalate.
- **Complementary interaction** — A pattern in which the participants' behaviours are complementary, stable, and mutually reinforcing.
- **Metacommunication** — A communication about a communication, carrying a commentary on the relationship in which it is transmitted.
- **Restoring content statements** — The clinical task of enabling a family to make statements that can be checked against reality.
- **You cannot not communicate** — The first of the rules of communication; every behaviour, including silence, is a message.
- **The communication audit** — The exercise in which a family member records the messages received and sent, so that a diffuse sense of being controlled becomes a specific and examinable set of statements.
- **The developmental double bind** — The requirement that the adolescent be a child in dependence and an adult in responsibility, in which every response is a symptom.
- **Reformulation of the referral** — The four-step procedure of taking the referral literally, examining the family's own efforts, identifying what the symptom accomplishes, and naming an alternative.
- **The "if you were me" question** — A strategic technique for adolescents that places the young person in the position of an expert and elicits their own solution.
- **The irreversibility of communication** — The rule that a message cannot be recalled and that a poorly worded remark will be understood and cannot be forgotten.
- **Directiveness with adolescents** — The strategic school's willingness to instruct rather than to explore, which some young people experience as respect and others as intrusion.

## 12. Chapter Summary

The strategic school began from the question of what maintains the problem now, and its answer — that a symptom continues because it solves something — produced a distinctive model and a distinctive repertoire. The problem-maintaining sequence is the central clinical object and is mapped in the family's own words with specific instances, and every element of the sequence is a candidate for change. The formulation of the symptom as a solution follows directly, and it ends in the identification of an alternative.

Communication theory supplied the analytic vocabulary. The double bind was described with its four conditions, and the observation was made that the developmental, the love–control, and the two-message forms are the ones that appear in work with adolescents. The symmetrical and the complementary patterns were described with the clinical consequence that the complementary patterns are the ones in which a problem is most easily maintained. The metacommunication was described, and the first substantive task in work with a family locked into a metacommunicative spiral was identified as the restoration of the ability to make content statements. The four rules of communication were set out with their clinical consequences, and the irreversibility rule was identified as a constraint on the practitioner's own conduct.

The techniques were described in detail: the enactment of the sequence, with its distinctive purpose of testing rather than merely diagnosing; the directive, with its attributes of specificity, attribution, and date; the paradoxical injunction; the paradoxical prescription; the ordeal, with the explicit statement that it is now discredited; the reframe, with its clinical test; the restriction; and the team of the strategic. The chapter was explicit about which of these survive into contemporary practice and which do not.

The adaptations for young people were described, with the four complaints, the "if you were me" technique, the extension of the sequence into the school, the caution about the paradoxical move, and the use of the restriction early. The risk of the symptom-as-solution formulation was named: that it can become an accusation, and that the discipline required is to hold the formulation at the level of the system rather than the level of the individual.

The case of Iris demonstrated the model. The referral — that she was refusing to grow up — was reformulated: she was trying to leave, and the only route she could see cost her mother the most. The sequence was mapped with Iris in the room, and the mapping revealed that the money was the vehicle for the mother's anxiety and not the problem itself. The reframe was offered to the mother as a hypothesis, and the directive — not to raise the money for two weeks — produced the conversation that the whole case needed. The outcome was functional rather than warm, and the practitioner said so to both parties.

The evidence was presented accurately: little controlled research on the model, weak support for its controversial techniques, good support for the family-based and systemic approaches that are strategic in their core, and the best-evidenced of the successors being the solution-focused work of Chapter 35. The strengths and limitations were set out, and the limitations included the accusatory risk, the ethically indefensible elements of the historical repertoire, the under-accounting of feeling, the thin evidence, and the under-accounting of the material and the structural.

The ethical analysis was substantial. The ethics of directive work were set out with the requirement that a directive be attributed, be for the young person or be agreed to, be safe, and be transparent in its purpose. The ethics of the team of the strategic were treated directly, and the three requirements of informed consent, understanding, and the right to end the arrangement were stated. The distinction between a reframe and a deception was drawn with the test of whether the practitioner would be willing for the young person to know how the formulation was reached. The cultural considerations addressed communication style, hierarchy and the standing of the professional's directive, the assumption that the family is the unit, the language and the metacommunication, and the economic framing — including the point that the practitioner's willingness to say that the money is not the real problem is a luxury in a setting in which it is.

## 13. Review and Discussion Questions

### Review and Discussion Questions

1. Explain the question the strategic school asked that the structural school did not.
2. Describe the development of the Mental Research Institute and the contribution of each member.
3. Define the problem-maintaining sequence and state the four requirements for mapping it.
4. Explain the "symptom as a solution" claim and its three parts.
5. State the four conditions of a double bind.
6. Describe the developmental, the love–control, and the two-message double binds with adolescents.
7. Distinguish symmetrical from complementary patterns and state the clinical consequence of each.
8. Define a metacommunication and explain the clinical significance of a family locked into metacommunication.
9. State the four rules of communication and the clinical consequence of each.
10. Describe the enactment of the sequence and explain how it differs from the structural enactment.
11. State the attributes of a directive and the six requirements of ethical directive work.
12. Explain the paradoxical injunction and the paradoxical prescription, and state the contemporary position on each.
13. Explain the ordeal and state why it is discredited.
14. Define a reframe and state the two tests of a defensible reframe.
15. Explain the restriction and why it is clinically useful early in the work.
16. Describe the team of the strategic and state the three contemporary requirements for its use.
17. State the four adaptations of the strategic model for adolescents.
18. Explain the risk of the symptom-as-solution formulation and the discipline required to avoid it.
19. State the four steps of the reformulation of the referral, and work through the Iris example.
20. Describe the case of Iris and state the three features of it that generalise.
21. Summarise the status of the evidence for the strategic model and for its descendants.
22. State the six strengths and the six limitations of the model.
23. State the distinction between a reframe and a deception, with its test.
24. State the five cultural considerations for strategic work.
25. Explain the ethical requirement that a young person who does not attend family work is treated as a systemic communication.

## 14. Practice Activities

### Practice and Application

### Activity 32.1 — Mapping a Sequence (90 minutes, field-based)

Take a problem you have actually encountered — your own, a friend's, a placement case — and map the problem-maintaining sequence in detail, in the specific terms in which it occurs, with dates and times. Then mark every point in the sequence at which a different response by a family member would produce a different outcome. Then write the single reframe that the sequence supports. Most students find that the sequence contains at least five change points, that the referral describes none of them, and that the reframe is easier to write once the sequence is mapped.

### Activity 32.2 — The Communication Audit (60 minutes, individual)

For one day, record the messages you receive and send in one family or one friendship, with the content and the metacommunication. Then identify the double binds you are in, if any, and identify the messages that cannot be commented on. Then write what a person in that family could actually do differently tomorrow, in one specific situation. The exercise is the fastest way to understand why a family cannot change a pattern, and it is usually unexpectedly humbling.

### Activity 32.3 — Writing a Directive (75 minutes, small group)

In groups of three, write a directive for a realistic adolescent situation. The group must specify: the exact behaviour, the date, the person to whom it is addressed, the attribution, what happens if it is not complied with, and what the directive is designed to test. Then rewrite it as advice, in order to see how much authority is lost. Then rewrite it so that it is covert, in order to see what is lost there, and discuss whether the second version is defensible. The third step is the important one, and the group discussion of it is usually the most valuable part of the exercise.

### Activity 32.4 — The Reframe Audit (60 minutes, individual)

Take a reframe that you have heard used in a placement, a staff room, or a supervision meeting, and audit it. Is it true? Is it more nearly true than the account in place? Does it serve the young person or the adults? Would the young person recognise it as an accurate description of their own experience? Would the practitioner be willing for the young person to know how the reframe was arrived at? The five questions are the chapter's ethical analysis compressed into an exercise, and they apply to every reframe a student will ever hear.

## 15. Annotated Reading Pathways

**For the communication theory.** Read Bateson and colleagues (1964) and then Watzlawick and colleagues (1967), which is the most quoted and most useful book in the family therapy field. The double bind and the metacommunication are best learned from the original formulations.

**For the model.** Read Haley (1963) and Madanes (1981). The later strategic work of the Milan group, in Andolfi and Canestri (2008), is the most useful contemporary account of the strategic tradition in practice.

**For the successor schools.** Read de Shazer (1985) and Walter and Peller (1992) for the solution-focused work of Chapter 35, and read the narrative therapy literature for Chapter 36. The strategic school's most successful descendants are more widely used than the school itself, and a student who knows the descendants will use the school's insights in a more defensible form.

**For the ethics.** Read the ethical guidelines for the family therapies and the critical literature on the team of the strategic and on the ordeals. The critical literature is essential and it is not difficult to find.

**For the evidence.** Read the family-based treatment evidence in the adjacent areas, and the solution-focused evidence. The strategic model is best understood through the evidence for what it contributed to.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Strategic Family Therapy and Communication Theory** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is problem-maintaining sequences, directives, and the reframing of the problem. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is family patterns, attachment, boundaries, communication, stories, and relational resources. The mechanism to keep in view is how interaction sequences and shared meanings distribute distress, protection, responsibility, and possibility across a system. The characteristic professional risk is blaming families, exposing a young person in unsafe joint sessions, or ignoring material conditions and individual needs. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 7. Apply the method | Use the chapter's core procedures in family meetings, school consultations, care networks, and individual sessions informed by systems thinking, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support,

timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Marcus is fifteen and is seen in a community adolescent clinic for school avoidance and rising panic. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Marcus's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Marcus explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on family patterns, attachment, boundaries, communication, stories, and relational resources. The first intervention is deliberately modest. Marcus chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Marcus has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Marcus can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be

sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Strategic Family Therapy and Communication Theory

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Strategic Family Therapy and Communication Theory** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

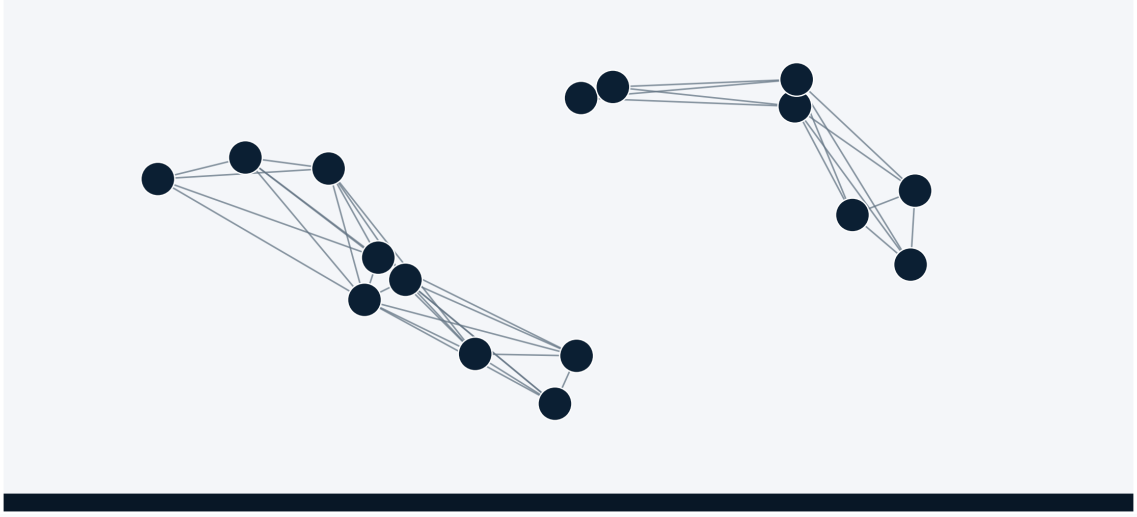
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Strategic Family Therapy and Communication Theory** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Strategic Family Therapy and Communication Theory**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a



discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Strategic Family Therapy and Communication Theory to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 33

# Family Therapy with Parents and Adolescents

Developmental and systemic consultation with families in conflict.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain why the parent–adolescent relationship is the central developmental relationship of the second decade of life, and why the work with the parents is the essential work.
- Describe the developmental tasks of the adolescent years and the parental tasks that correspond to them.
- Explain the parent training literature and the behavioural analysis of the parent–adolescent interaction cycle.
- Describe the mainstream and conflict patterns of parent–adolescent communication and the clinical significance of each.
- Apply the principles of developmental and systemic consultation to a school or clinic case involving a young person and their parents.
- Design a parent-focused intervention for a case of adolescent non-compliance or conflict, including the components and the sequencing.
- Critically evaluate the cultural and ethical dimensions of work with parents in the adolescent years, including the question of whose problem the work addresses.

## Chapter Overview

This chapter is the practical centre of Part V, and it is the chapter in which the preceding three theories are brought together around a single clinical situation: a young person and their parents in conflict.

The argument of the chapter is simple and it is the most important thing in this part of the book. **When a young person and their parents are in conflict, the parents are the more tractable target.** This is not a value judgement about who is more important. It is a statement about what a practitioner can actually work with. The parents are adults, they are available, they are generally motivated by the referral, and the relationship between them and the young person is the mechanism through which everything else operates. A young person who is caught in the middle of a conflict between two adults cannot think, cannot develop, and cannot use the therapy; the adults can.

The developmental literature makes the same point from the other direction. The adolescent's task is a renegotiation of the relationship with the parents, and the renegotiation is a *developmental* task that can only be completed if the parents make the renegotiation possible. A young person cannot unilaterally leave the child subsystem; the parents hold the key to the door and, if the door stays locked, the young person's options are to force it, to break it, or to give up and stay.

The chapter therefore covers: the developmental rationale; the parent training literature and the behavioural analysis of the escalation cycle; the communication patterns and their clinical significance; the practical structure of a parent-focused intervention; the consultation relationship with the school; and the ethical and cultural analysis, which is substantial because the work with parents raises the question of whose difficulty is being treated.

## 1. The Developmental Rationale

## 1.1 The second decade

The period from approximately ten to twenty is the period in which the young person becomes a person rather than a child, and the mechanism is the renegotiation of the relationship with the parents. This is a period of enormous change in the young person's cognition, in which the ability to think hypothetically and to reason about other people's states develops rapidly, and it is a period in which the peer world becomes the primary arena of development.

The developmental literature gives four accountabilities to the parents during this period, and each is a task that can be observed and worked on.

**To provide a base of secure attachment that the adolescent can gradually relinquish.** The adolescent needs a secure base to move out from, and the secure base is not a helicopter parent; it is the reliable, non-intrusive availability of an adult who is not frightened of the adolescent's development.

**To maintain the parental authority that the adolescent needs.** The authority question is the one that generates most of the conflict in this period, and the adolescent's developmental task is to test the limits of the parental authority, and the parents' task is to hold the limit without needing to win. A parent who cannot hold a limit without a fight will lose the developmental negotiation.

**To provide a structure that is firm enough to be safe and flexible enough to grow into.** The adolescent needs a structure that increases in responsibility as the capacity increases, and a structure that does not increase in responsibility produces a young person who cannot manage, and a structure that increases too fast produces a young person who cannot cope.

**To maintain a relationship with the adolescent that is not the same as the relationship with the child.** The parents have to be able to relate to a person who is not the child they had, and the parental task of mourning the child is routinely skipped, and the young person experiences the mourning as rejection.

## 1.2 The mismatch and the symptom

The clinical presentation in this period is very often a **structural mismatch**: the parents are operating a pre-adolescent structure over an adolescent child, and the symptom is the report of the mismatch. The report is in the language of behaviour — the arguments, the slammed doors, the refusal, the secretiveness, the risk-taking, the disappearing — because the young person has no other channel through which to say "the rules here are for a younger person than I am".

This is the diagnosis that the structural model of Chapter 31 makes most precisely, and it is very frequently the correct one. The clinical test is simple and a student should be able to apply it: **compare the demands and the expectations the parents are making with the developmental capacity of the specific young person.** The demands for a fourteen-year-old's contribution to the household, the expectations about curfews, about the use of the phone, about disclosure, about the treatment of the parents' requests, about the sharing of information — these are the variables.

## 1.3 The task of the practitioner

The practitioner's task in this period has three parts, and they are in a definite order.

**First, to establish what the parents want.** Not what they say they want in the referral, which is usually the symptom's removal, but what they want for the young person's life. Almost every parent in this period wants something they cannot say, because saying it would be to acknowledge that the family is not in the state

they have described. A mother who refers her fifteen-year-old for "attitude" and who actually wants a relationship in which her daughter tells her about her life is a mother who can be worked with, and a mother who wants the daughter to obey is a mother who can be worked with differently.

**Second, to help the parents make the changes that the developmental situation requires.** This is the work, and it is the work with the adults.

**Third, to work with the young person** on the developmental tasks that the improved family environment makes possible.

# 2. The Parent–Adolescent Interaction Cycle

## 2.1 The behavioural analysis of conflict

The parent training literature produced one of the most thoroughly validated findings in the child behavioural literature: the **escalation cycle** in which oppositional and antagonistic behaviour between parents and children is maintained by a predictable sequence of responses, and the sequence is not the one the parents intend.

The cycle runs as follows. The parent makes a request. The child refuses. The parent repeats the request, with escalating insistence, with warnings, with increased volume, and often with the addition of a threat. The child escalates in response. The parent then backs down, either explicitly, or by changing the subject, or by shouting and then leaving, or by threatening a consequence that does not arrive. The child's escalation has produced the parent's withdrawal, and the withdrawal is the reinforcement.

The sequence has three features that a practitioner should be able to name.

**The escalation is a communication.** It is a bid for attention, for a change of activity, for a delay, for help, or for the removal of the demand, and it is the only bid available if the polite bid has been ignored.

**The parent's escalation is the trigger for the child's.** A parent who increases the volume produces a child who increases the volume, and the increase is not a character trait; it is a reaction to a reaction.

**The parent's backing down is the reinforcement.** The behaviour that ends the battle is the behaviour that is rewarded by the end of the battle, and the reward is the removal of the demand, which is the most reliable and most reinforcing consequence available in the situation.

## 2.2 The parent training evidence

The parent training literature is the strongest evidence in the field for the claim that parental behaviour is a tractable target, and the findings are consistent.

**Parent training has a robust effect on oppositional behaviour and on conduct problems**, and the Cochrane reviews report substantial and durable effects, and the effects are maintained at follow-up.

**The improvements are broad.** Parent training produces improvements in the child's oppositional behaviour, in the parent's distress, in sibling conflict, in the family's functioning, and in some studies in the child's academic performance.

**Parent training works best when the parent's behaviour changes and when the family is engaged with the work**, and the fidelity of the parent's use of the techniques determines the outcome.

**Parent training works less well with young people who are severely antisocial**, and the pattern of the research is that the interventions work better with younger children and with less entrenched patterns.

**The sessions with the parents are the sessions.** Almost all parent training programmes involve the parents alone for the core of the work, and the child is not in the room.

### 2.3 The skills parent training teaches

The core content of the parent training that has the best evidence is short and teachable.

**Positive reinforcement and attention.** The parent learns to attend to the desired behaviour promptly, specifically, and with a description of what the child did, and to increase the attention to the desired behaviour relative to the undesired.

**Ignoring and planned ignoring.** The parent learns to withdraw attention from the undesired behaviour, genuinely, without a verbal signal, and the parent learns that the withdrawal is temporary and that the behaviour will get worse before it gets better.

**Time-out from reinforcement** and **response cost**, taught with the specific rules that make them safe and effective.

**Consistency between the adults**, which is the most commonly neglected and most necessary element, and which requires the practitioner to work with every caregiver who has significant contact with the young person.

**The skill of talking rather than shouting**, taught through modelling, role-play, and behavioural rehearsal.

**The "catch them being good" practice**, which is a specific, concrete, and effective technique: the parent is instructed to notice, describe, and respond to every instance of the desired behaviour, and to record them, and the recording is what makes the noticing systematic.

### 2.4 A caution about the behavioural model of parenting

The parent training literature is the strongest evidence base in the field, and it is also the literature with the strongest cultural and moral assumptions, and a student should be able to state the concern.

The model treats the parent's attention as a resource to be allocated according to a set of technical rules, and it treats the child's behaviour as a set of responses to be selected. Two consequences follow. First, the young person is understood as a set of behaviours to be managed rather than as a developing person with a point of view, and a practitioner who works exclusively in this frame will produce a compliant young person and a distressed relationship. Second, the model sits uncomfortably with a body of evidence and ethical argument that the consistent use of reinforcement and the withdrawal of attention is a form of conditioning that is appropriate for a behaviour and inappropriate for a relationship.

The resolution is the one that the evidence itself supports: parent training works when it is used to increase the *quality* of the relationship, not to increase the *compliance* of the child. The techniques that improve the relationship — attending to what the child is doing well, describing it specifically, being consistent, being calm — are the same techniques. The difference is in what the practitioner is trying to achieve with them, and the difference is observable in the outcome.

## 3. Communication Between Parents and Adolescents

## 3.1 The mainstream and the conflict pattern

The developmental literature on parent–adolescent communication identifies a **mainstream pattern** of good communication and a **conflict pattern** of poor communication, and the characteristics of each are the basis of the assessment.

The **mainstream** is characterised by the parents listening without interruption; by the parents being accepting of the young person's feelings even when they disapprove of the behaviour; by the parents acknowledging the young person's point of view as a legitimate one; by the parents being reasonably consistent; by the young person disclosing; by the parents being involved in the young person's world; and by the parents showing a mild sense of humour.

The **conflict pattern** is characterised by the parents' frequent criticism; by the parents' hostility and their belittling of the young person; by the parents' physical punishment; by the parents' inconsistent discipline; by the young person's withholding of information; by the young person's refusal to talk; by the young person's escape from the family; and by the young person's physical and verbal aggression outside the home.

The patterns are almost perfectly correlated with the outcomes, and the correlation is large. A student should know the list and should be able to use it as an assessment instrument in the first session, because the two patterns are readily observable in a single family session.

## 3.2 The disclosure process

The literature on adolescent disclosure identifies a developmental sequence with direct clinical implications.

**The early childhood phase** (approximately six to twelve) is one of high parental control and high disclosure, in which the parents determine what is disclosed and the young person does not select.

**The early adolescence phase** (approximately twelve to fifteen) is one of decreasing parental control and a shift towards peer orientation, in which the young person's disclosure to the parents declines and the parental knowledge of the young person's world declines with it. The developmental task of this phase is described as **detachment from parental control**, and it is a normal and necessary stage.

**The middle adolescence phase** (approximately fifteen to seventeen) is one of increasing peer orientation and of the development of an **individualised system of beliefs, values, and perceptions** that is often incompatible with the parents'. The developmental task is the development of an independent moral and value system, and the young person needs to have arguments in order to do it, and the arguing is the work, not the failure.

**The later adolescence phase** (approximately seventeen to twenty) is one of a gradual re-establishment of a relationship with the parents that is more equal and more companionate, and the relationship that eventually forms is the one in which the young person can disclose.

Two clinical conclusions follow, and they are important.

**The decline in disclosure during early adolescence is normal and is not a problem to be solved.** A practitioner who treats the young person's refusal to tell the parents about their weekend as a symptom is doing something harmful, and a parent who experiences it as a symptom will respond with intrusion, and the intrusion produces more withdrawal. The developmental task is detachment from parental control, and the parent's task is to allow it.

**The young person's arguments in the middle adolescent years are part of the work.** The developmental literature is unusually clear that the "who owns me" arguments are necessary for the development of an individualised value system, and that a parent who wins these arguments wins them at the cost of the young person's development. The parent's task is to survive them, and to set the limits on the *form* of the argument while not requiring the young person to abandon the content.

### 3.3 The three common conflicts

Three conflicts recur in clinical work, and each has a different clinical character.

**The autonomy conflict.** The young person is asserting control over choices — clothing, friends, music, the use of the phone, the choice of clothes, the choice of music, the choice of friends, the choice of what to wear, the choice of where to go, the choice of which music to listen to, the choice of which friends to see. The underlying developmental issue is the differentiation of self, and the parental contribution is usually the overreaction. A parent who treats a preference about clothing as a challenge to authority produces a fight in which neither the clothing nor the authority is really the point.

**The sexuality conflict.** This conflict, which arises in the context of the family's boundaries, the young person's emerging sexuality, the family's cultural and religious values, the parents' own relationship with their own bodies, and the question of privacy, is unusually charged and it requires cultural competence rather than technical skill.

**The achievement conflict.** The young person's performance in school is the site of the parents' own histories, their own educational experience, their own social class, and their own comparative standing. This conflict is frequently a conflict between the young person and the parent's projected self, and it is the conflict in which the family therapy work is most clearly indicated, because the parents' investment in the young person's achievement is not the young person's own.

# 5. The Practice of Parent–Adolescent Work

## 5.1 The first session: the parents alone

The first session is with the parents, and it is the session in which the work is determined, and it has a specific structure.

**The referral and the actual request.** The practitioner asks what the parents hope will be different, and then asks the question that reframes the session: "And what do you want for [the young person's name] in three years' time? Not what you want them to stop doing — what you want their life to look like." The two questions usually produce different answers, and the second is the one the work is built on.

**The developmental timeline.** The practitioner asks the parents to describe their child's development, from the earliest years they can remember, and the narrative does a great deal of the work. Parents who describe a child who was always difficult are describing a child they have never had a relationship with; parents who describe a child who was easy until a particular point are identifying the point at which the difficulty began, and the point is often the point at which the developmental task changed and the parental structure did not.

**The pattern.** The practitioner asks about a specific recent instance, and gets the sequence, using the material of Chapter 32. The sequence is the most useful single artefact of the assessment, because it is specific, and because it identifies the change points.

**The escalation.** The practitioner asks the parents to describe what they do when the young person refuses. The answer is the escalation, and most parents have not heard themselves describe it.

**The parents' own lives.** The practitioner asks what has been happening in the parents' own lives over the last year. A new job, an illness, a bereavement, a debt, a pregnancy, a separation, a new baby, a move, a caring responsibility for an older relative. The list of things that can precipitate a family crisis in this period is short, and the practitioner should have it in mind, and the answer is frequently that something has

happened.

## 5.2 The five components of a parent-focused intervention

**Component one: the psychoeducation.** The parents are told what the developmental task is and what the developmental timetable looks like, and the specific points about the decline in disclosure, the arguing, and the detachment from parental control are explained. The explanation is not to make the parents feel guilty; it is to remove the interpretation that the young person's behaviour is a rejection of them, which is the interpretation that generates the escalation.

**Component two: the reconstruction of the sequence.** The parents and the practitioner map the escalation cycle together, on paper, in the session. The map is the therapeutic instrument, because the parents can see the cycle only once it is drawn. The practitioner should expect the moment of recognition, and it is often the most important moment in the whole course of work, and it is also the moment at which a parent becomes hopeful, because the cycle implies that it can be interrupted.

**Component three: the skills.** The parent training content is taught: positive reinforcement, attention to the desired behaviour, planned ignoring, time-out from reinforcement, consistency, and the "catch them being good" practice. The skills are taught by rehearsal, not by discussion, and the rehearsal is the reason parent training works better than information about parenting.

**Component four: the renegotiated structure.** The specific changes to the rules: the curfews, the phone, the privacy, the contribution to the household, the disclosure, the consequences. The changes should be written down, agreed, and dated, and they should include an explicit statement of what the young person gets as well as what is required. A set of rules that only restricts is a set of rules that will be breached.

**Component five: the relationship work.** The most important and the most neglected component. The parents and the young person need a relationship that is not the one in which the conflict occurs, and the work is on the *quality of the connection* rather than on the *management of the behaviour*: the specific daily contact, the specific appreciation, the specific time, the specific activity. A father who has a Saturday morning hour with his fifteen-year-old son and does something the son chooses has built something that the token of a good week of compliance cannot buy.

## 5.3 Sequencing: the parents first

The sequencing follows from the developmental reasoning and should be defended to the referrer if the referral expects to see the young person in the first week.

**Weeks 1–4: the parents.** The psychoeducation, the sequence, the skills, the renegotiated structure. The young person is seen briefly and individually in parallel, for the alliance and for the developmental work.

**Weeks 5–8: the parents and the young person together.** The renegotiated rules are made explicit, the young person is given a real role in the negotiation, and the practical arrangements are settled.

**Weeks 9 onward: the work with the young person**, which can now proceed because the environment has changed.

The strongest practical argument for this sequence is empirical: a young person who is asked to change while the adults who control the environment are not changing will conclude that the adults are not serious, and the conclusion will be correct, and the young person's cooperation will be withdrawn. A young person who is asked to change after the adults have changed will conclude that the change is real, and the

conclusion will also be correct, and the young person's cooperation will be available.

## 5.4 When the parents will not work

Sometimes the parents will not or cannot do the work, and the practitioner needs a plan.

**The parents are the problem.** In a minority of cases the young person is the least disturbed member of the family, and the work is with the parents' own difficulties. The practitioner should be able to identify this situation, and the referral should be redirected rather than the work being forced.

**The parents cannot agree.** A common situation is that the two parents want different things. The work is then directed at the *disagreement*, and a common and effective intervention is to help the parents reach an agreement about the rules as a preliminary to anything else. Parents who cannot agree on a curfew cannot implement a curfew.

**The parents are overwhelmed.** A family with three jobs, no transport, and a young person with additional needs cannot undertake a skills programme. The response is to reduce the intervention to its minimum viable form: one specific rule, changed, consistently applied.

**The young person refuses to participate.** The work continues with the parents, and the young person's refusal is treated as information, and the practitioner maintains a separate channel with the young person.

## 5.5 Consultation with the school

Almost every case of adolescent conflict involves the school, and the school is usually where the young person's difficulties are most visible and where the parents' changes are least likely to be supported. The consultation work has four elements.

**The school's account of the behaviour.** The behaviour in the corridor, in the classroom, and in the dining hall may look entirely different from the behaviour at home, and the school is a different system with different contingencies.

**The alignment of the responses.** If the parents have made a new rule and the school has a different one, the young person will be confused and will be given the opportunity to play the two against each other. The alignment should be explicit and should be written down and shared.

**The information flow.** The school is a source of information about the young person, and the practitioner must decide what is shared with the school and what is not, and the young person must know, and the consent requirement is absolute. In most cases, the young person's grades, the school reports, and the practitioner's observation are shared with the parents and not with the school, unless the young person agrees.

**The teacher's needs.** The teacher is dealing with the behaviour in the classroom, and the teacher needs something concrete. A specific plan for the classroom — a specified response to the disruption, a specified alternative the young person can use, a specified signal for help — is worth more than a general reassurance.

**Developmental Tasks and the Parent-Adolescent Tension**

| Developmental task of the adolescent | Typical parental worry | Constructive counselor stance |
|---|---|---|
| Autonomy and independence | Loss of control, loneliness, risk | Separate the person from the conflict |
| Identity formation | Loss of influence over who the child becomes | Support exploration without fixating an outcome |
| Peer and romantic relationships | Values, loyalty, reputation | Hold the boundaries that matter, negotiate the rest |
| Risk and sensation seeking | Physical danger, moral failure | Distinguish safety from disapproval |
| Sexual and romantic development | Abandonment, vulnerability | Provide accurate information without intrusion |

*Most family conflict with adolescents is a developmental artefact rather than a pathology.*

**Figure 33.22** The parent–adolescent relationship shown in three domains, with the parental tasks, the adolescent tasks, and the points of conflict identified for each developmental phase.

### 5.6 Working with the young person directly

The work with the young person is not only a phase that comes later. Several interventions can be delivered directly.

**The developmental work.** The practitioner works with the young person on the specific tasks of the period: the separation from the parental system, the development of an individualised value system, the development of the peer world, the toleration of the inevitable arguments. The work is developmental and it is not reducible to a coping skill.

**The relationship with the young person as a buffer.** Even where the parents cannot change, the practitioner can be the adult in the young person's life who is reliable, non-intrusive, and available, and the young person's experience of being able to trust an adult is itself a protective factor and a developmental achievement.

**The work on the specific difficulty.** Where the young person's difficulty is a symptom — the anxiety, the depression, the eating, the substance use — the specific treatment is delivered in parallel, and Chapter 38 and Chapter 47 address the complex cases.

**The mediation.** Where the parents cannot work together, the practitioner can work with the young person and one parent on the relationship, and the work can produce a change in the dyad that the family system then accommodates.

## 6. Case Illustration: The Young Man Who Had Been Given Ultimatums

**Presentation.** Samuel is fifteen and lives with his mother and his younger sister. He is referred by the school, which is concerned about his behaviour in lessons. His mother attends the first appointment and is, in the practitioner's word, "furious and frightened in about equal measure". The referral describes a young man who is argumentative, who does not do his homework, who is "rude" to his mother, and who has

recently been excluded twice.

**The first session with the mother.** The practitioner begins with the question that reframes the session: "What do you want for Samuel in three years' time?" The mother says, without hesitation: "I want him to go to university. I want him to have what I didn't have." The practitioner asks what she wants him to stop doing, and the mother says: "The arguing. The rudeness. The not doing his work."

The two answers are in different places and the difference is the whole case. The mother's stated goal is a future, and it is a future she has a strong investment in, and it is a future in which Samuel is the vehicle for the repair of her own history. The referral question is about the present, and it is about compliance.

**The sequence.** The practitioner asks the mother to describe a recent argument in detail. What emerges is a highly patterned exchange. Samuel comes in at nine; his mother asks him about his day; he says "fine"; she asks again; he says "I said fine"; she says "don't talk to me like that"; he says "what do you want me to say, mum"; she says "the truth"; he says "there's nothing to say"; she raises her voice and says "don't give me that attitude, I've had enough, you're going to sit at that table until you've done your work"; he goes up to his room; she calls up after five minutes; he does not answer; she says "fine, be like that"; and the evening ends with both of them certain that the other is the problem.

The practitioner maps it on paper, with the mother, and the mother's face changes when she sees it. The sequence is recognisable: the repeated question after "fine", the "don't talk to me like that", the demand that he produce an emotion he does not have, the ultimatum about the table, the five-minute silence, and the withdrawal. And then the practitioner asks the critical question: "What happens if he does sit at the table?" The mother says: "He doesn't. He just talks." The practitioner asks: "So what does he get by not sitting at the table?" The mother thinks and then says, with some surprise: "He gets to be upstairs."

**The formulation.** Samuel's refusal is maintained by escape. He is not in conflict with his mother; he is a young man who has discovered that a specific sequence of exchange delivers him to his room, and the room is where he wants to be, and it is the only thing in his day that is reliably his. The mother's ultimatums are the problem, and they are also the solution — they are the family's only route to the room, and they have taught Samuel that the negotiation is the way to get there.

**The intervention with the mother.** Four elements.

*Element one: the developmental frame.* The practitioner explains the mid-adolescent phase: the arguing, the testing, the increasing need for an individualised value system, the decline in disclosure, the detachment from parental control. The explanation is delivered with the developmental literature, and it is delivered as information rather than as correction, and the practitioner is careful to say that the arguing is necessary and is not going to stop.

*Element two: the restriction.* The practitioner gives the mother a specific instruction: "For the next two weeks, you are not going to ask him a second time about anything. If he says 'fine', that is the end of the conversation about his day. If he says nothing, that is also the end. The only exception is the question about the work, and the work question is going to be a different conversation, and I will show you how."

The reasoning is given explicitly: the repeated question is the hook, and the young man is not resisting the question, he is resisting the repetition, and the repetition is what gives him the opening.

*Element three: the work question.* The practitioner spends twenty minutes with the mother on how to ask about the homework, and the difference is technical but decisive. "How's the homework?" produces "fine" and then a confrontation. "What did you get through on the maths?" produces a description. The second

question cannot be answered with "fine" and it does not require the young person to produce a feeling, and it opens a conversation about a specific thing.

*Element four: the negotiation with Samuel.* The practitioner meets Samuel alone and explains what is happening, in terms that do not disclose his mother's account of the sequence: "Your mum and I have been looking at what happens when she asks you about your day. You've probably noticed that when she asks twice, things get worse. She's going to try asking once and then leaving it. I wanted you to know it's happening so it doesn't feel like a trick." Samuel considers this and says: "She'll forget." The practitioner says: "Probably. And then you can tell her, and we'll do it again."

**The outcome.** The change is visible in three weeks. The arguments stop; what replaces them is silence, and the practitioner explains to the mother that silence is a good outcome here, because the silence is the absence of a fight rather than the presence of a wall. Samuel comes down of his own accord more often, and the work gets done more often, and the two of them have a relationship that is not warm but is not combative. The school reports an improvement in the lessons, though less dramatic than the mother hoped, and the practitioner is careful to say why: the school is a different system and the changes have to be made there too, and the consultation with the form tutor is what produces them.

**The interpretation.** The case illustrates the whole of the chapter. The referral was about compliance. The problem was the escape contingency that the mother's ultimatums had created. The work was with the mother, because the mother was the tractable target, and because the developmental argument was the thing that changed her behaviour. And the practitioner did the thing that is hardest in this work, which was to tell the mother that the arguing would not stop, and that the goal was a different relationship and not the elimination of the disagreement.

# 7. Evidence and Research Support

## 7.1 The status of the evidence

The evidence for parent-focused work with adolescents is the strongest in the field, and a student should be able to summarise it precisely.

**Parent training has a robust effect on oppositional behaviour and conduct disorder**, and the Cochrane reviews report substantial effects, maintained at follow-up, and the effects are larger for younger children than for adolescents.

**Parent training improves the parent's own symptoms of distress**, and the parental depression and the parental stress are among the better-established effects, which is one of the strongest arguments for the approach, because the parent's distress is what maintains the escalation.

**Parent training is effective in school-based formats**, and the evidence for the school-based delivery of parent training is good, and the school-based formats are more accessible to families who cannot attend clinic appointments, and the evidence for the telephone and the online formats has grown.

**Behavioural family therapy, which combines parent training with the teaching of problem-solving and communication skills, has a strong evidence base**, and the Cochrane reviews of behavioural family therapy for conduct problems report large effects.

**Family-based treatment of adolescent substance use has good support**, and the family-based approaches consistently outperform the individual approaches in this population.

**Parent-focused interventions improve the young person's functioning as well as the behaviour**, and this is one of the more important findings, because the changes in family functioning are what make the behaviour change durable.

**The effects are smaller for adolescents than for younger children**, and the pattern of the research is that the more entrenched the pattern and the older the young person, the smaller the effect.

### 7.2 The limitations of the evidence

**The studies are largely North American and European**, and the cultural specificity of the parenting constructs in them is significant.

**The samples are selected**, and the families who complete parent training are more engaged and less disadvantaged than the families who are referred.

**The measures are largely behavioural and parental-report**, and the young person's own account of the change is less often measured.

**The long-term follow-up is limited**, and the question of whether the effects are maintained into the adult years is largely unanswered.

**The studies rarely examine the mechanism**, and it remains difficult to specify which components of the parent training package are responsible for the effect.

## 8. Strengths and Limitations of Parent-Focused Work

### 8.1 Strengths

**It works.** This is the strongest empirical claim that can be made for any intervention with adolescents and their families, and it is unusual in this field.

**It addresses the adults who control the environment.** A young person cannot change a household; a parent can.

**It is deliverable in schools and in primary care**, and it is deliverable by non-specialists with supervision, and the evidence for the supervised delivery is good.

**It is short.** Parent training is typically between eight and sixteen sessions, and brevity is a clinical advantage with a population that does not stay.

**It improves the parents**, and the parents' improvement is a durable benefit even if the young person's symptoms recur.

**It does not require the young person to be motivated.** This is a significant advantage: a young person who is not engaged can still benefit from a change in the environment.

### 8.2 Limitations

**It can be used in ways that are not therapeutic.** The techniques of parent training can be used to produce compliance in a young person whose problem is not compliance, and the field has a genuine responsibility here.

**It can locate the problem in the parent when the problem is elsewhere**, and this is the principal risk of the approach.

**It says little about the young person's own experience**, and a practitioner working exclusively in the parent frame will produce a family that functions and a young person who is not seen.

**The effects on adolescents are smaller than on younger children**, and the hardest cases are the ones that most need it.

**It assumes a stable, cooperative, two-parent family**, and a substantial proportion of the families in contemporary services are neither stable nor cooperative nor two-parent.

# 9. Cultural and Ethical Considerations

## 9.1 Whose problem is being treated?

This is the central ethical question of the chapter, and it should be asked in every case.

When a young person is referred for conflict with their parents, the referral frames the young person as the problem. The ethical work is to establish whether the young person is the problem, the parents are, the family system is, or the circumstances are. Four different interventions follow, and a practitioner who does not make the distinction will deliver the wrong one.

**The young person is the problem.** The conflict is a symptom of the young person's difficulties, and the parents need support in managing a difficult developmental period, and the work with the young person is the primary work.

**The parents are the problem.** The young person is the least disturbed member of the family, and the work is with the parents, and the young person's needs are secondary to the parents' in this particular case.

**The family system is the problem.** The conflict is the family's; the young person is the site.

**The circumstances are the problem.** The conflict is a rational response to conditions — poverty, a disability, a housing crisis, a shift pattern, a family member's illness, a school that is unsafe. A parent who is working two jobs and is raising a disabled child alone and is being told by the school that her son is "difficult" is not a parent with a parenting problem.

A practitioner who does not ask the fourth question will systematically misdiagnose the families who most need help.

## 9.2 Cultural considerations

**The parenting norms of the practitioner are not the parenting norms of the family.** The practices that the parent training literature treats as effective — the daily attention, the specific praise, the consistent response, the clear rules, the negotiated decision-making — are specific to a particular cultural and historical context, and many families use other systems that work.

**Some of the most "effective" practices are the most damaging across cultures.** A parent who has been taught to withdraw attention as a response to a child's bid may, in a context where the child's bid is a call for connection in a context of scarcity, be withdrawing the very thing the child needs. The practitioner must know the family's context before implementing the ignoring techniques.

**Authoritative versus authoritarian.** The parenting literature's preferred style is authoritative — high in warmth and high in structure — and the style is a culturally specific form, and a family that is authoritative in its own terms may be described by an observer in the field's terms as authoritarian.

**The father's role.** The evidence base and the practice of parent training have been developed disproportionately with mothers, and the involvement of fathers is consistently lower than it should be, and a programme that does not include the father in a family where the father is present and available reproduces a structural problem.

**Language and the training materials.** The parent training materials are written in a particular register and a particular idiom, and a family whose first language is different will need the concepts translated and the materials adapted, and a practitioner who hands over a translated leaflet has not adapted the intervention.

### 9.3 Ethical requirements

**Informed consent from the parents and, where the young person is engaged, their informed participation.** A parent who consents to a skills programme under the impression that it will make their child comply has been misled.

**The young person's right to be heard.** Even where the work is with the parents, the young person's account must be sought, and it must be sought by someone the young person trusts.

**Confidentiality.** The boundaries between the individual work with the young person and the family work must be explicit and must be stated to everyone, and the practitioner must be able to state what will be shared with the parents and what will not.

**The prohibition on the use of the work to control.** A practitioner should decline a referral whose stated purpose is to obtain compliance, and should say why, and should offer the alternative.

**Proportionality.** The intervention should be proportionate to the difficulty, and the practitioner should resist the temptation to impose a full programme on a family with a small and specific difficulty.

**Equity of access.** Parent training delivered in a clinic to families who can attend is a service that will systematically under-reach. The school-based, the telephone, and the online formats exist because of this, and a practitioner in a service with a poor attendance record should be actively looking for them.

## 10. Key Terms

**Key Terms at a Glance**

- **Parent–adolescent conflict** — The friction between the parents and the adolescent in the second decade, which is a normal feature of the developmental renegotiation and becomes a clinical problem when it is escalating and the relationship is deteriorating.
- **The developmental task of the second decade** — The renegotiation of the relationship with the parents through which the young person becomes a person rather than a child.
- **The four parent accountabilities** — To provide a secure base that can be relinquished, to maintain the authority the adolescent needs, to provide a structure that is firm and flexible, and to maintain a relationship with the young person that is not the one they had as a child.
- **The parental task of mourning the child** — The work of relating to the young person the adolescent has become, which is routinely skipped and is experienced by the young person as rejection.
- **Escalation cycle** — The patterned sequence in which the parent's escalation produces the child's escalation and the parent's backing down then reinforces the child's.
- **The three features of the escalation cycle** — The escalation is a communication, the parent's escalation triggers the child's, and the parent's backing down is the reinforcement.
- **Parent training** — A structured programme of behavioural and communication skills for the parents, delivered in groups or individually, that has the strongest evidence base of any intervention with families.
- **Positive reinforcement and attention** — The parent skills of attending promptly and specifically to the desired behaviour, with a description of what the child did.
- **Planned ignoring** — The complete and temporary withdrawal of attention from a behaviour, taught with the expectation of an initial increase.
- **Time-out from reinforcement** — A specified removal of access to reinforcement contingent on a behaviour, taught with the rules that make it safe and effective.
- **Consistency between the adults** — The agreement of all caregivers who have significant contact with the young person, which is the most commonly neglected and most necessary element of the work.
- **The "catch them being good" practice** — The systematic noticing, describing, and responding to instances of the desired behaviour, with a record.
- **Mainstream communication pattern** — The characteristics of good parent–adolescent communication, and the profile of the families with better outcomes.

### Key Terms at a Glance (continued)

- **Conflict communication pattern** — The characteristics of poor parent–adolescent communication, and the profile of the families with worse outcomes.
- **The four phases of disclosure** — High control and high disclosure in early childhood, decreasing parental control and declining disclosure in early adolescence, peer orientation and the development of an individualised value system in middle adolescence, and the re-establishment of a more equal relationship in later adolescence.
- **Detachment from parental control** — The early adolescent developmental task, and the reason the decline in disclosure is normal rather than a symptom.
- **The individualised value system** — The middle adolescent developmental task, and the reason the arguments are part of the work rather than evidence of its failure.
- **The three common conflicts** — The autonomy conflict, the sexuality conflict, and the achievement conflict, each with a different clinical character.
- **The achievement conflict** — The conflict over the young person's school performance, which is frequently a conflict with the parent's projected self.
- **Reformulation of the request** — The clinical move of distinguishing the parents' request for the removal of a behaviour from their wish for the young person's life.
- **The reconstruction of the sequence** — The mapping of the escalation cycle on paper with the parents, which is the therapeutic instrument of the parent-focused work.
- **The renegotiated structure** — The specific, written, dated set of changes to the household rules, including what the young person receives as well as what is required.
- **The relationship work** — The component directed at the quality of the connection between the young person and the parents, as distinct from the management of the behaviour.
- **Sequencing the parents first** — The clinical sequence in which the parents' work precedes the family's joint work, and the empirical basis for it.
- **The minimum viable intervention** — The reduced form of parent work, consisting of one specific rule changed and applied consistently, for families who cannot undertake a full programme.
- **The parent's disconfirmation** — The repeated question, the demand for a feeling, and the ultimatum, and their role in producing the confrontation.
- **The "what did you get through on the maths" question** — A specific formulation that cannot be answered with "fine" and that opens a conversation about a particular thing.

**Key Terms at a Glance (continued)**

- **Consultation alignment** — The requirement that the rules and responses in the school match those in the home, and the written record of the alignment.
- **The school's own contingencies** — The different reinforcement structure of the school setting, which requires its own functional analysis and its own plan.
- **Whose problem is being treated** — The ethical question of whether the young person, the parents, the family system, or the circumstances constitute the problem, and the four different interventions that follow.
- **The circumstances as the problem** — The category in which a young person's behaviour is a rational response to material conditions, and the failure to consider it that misdiagnoses the families most in need.

## 11. Chapter Summary

This chapter brought the three preceding theories together around the central clinical situation of this part of the book, and its governing argument is that when a young person and their parents are in conflict, the parents are the more tractable target. The argument is developmental rather than moral: the adolescent's task is a renegotiation of the relationship with the parents, the young person cannot unilaterally leave the child subsystem, and the adults hold the door.

The developmental rationale was set out with the four parent accountabilities, and the clinical presentation was described as a structural mismatch — the parents operating a pre-adolescent structure over an adolescent child — with a simple clinical test: compare the demands with the developmental capacity of the specific young person. The three-part task of the practitioner was described, and the most important element was the clarification of what the parents actually want, which is almost never the removal of the behaviour.

The behavioural analysis of the escalation cycle was described in detail, with its three features, and the parent training evidence was summarised, including the breadth of the effects and the finding that the sessions with the parents are the sessions. The core skills were described, and a substantial caution was given: the model treats the parent's attention as a technical resource, and a practitioner who works exclusively in that frame will produce a compliant young person and a distressed relationship. The resolution proposed was that parent training works when it is used to increase the quality of the relationship rather than the compliance of the child, and that the techniques are the same.

The communication material was described with the mainstream and conflict patterns as an assessment instrument usable in a single family session, and the four phases of disclosure with the two clinical conclusions that follow: the decline in disclosure in early adolescence is normal and is not a symptom to be treated, and the arguments of the middle adolescent years are part of the developmental work rather than its failure. The three common conflicts were described, and the achievement conflict was identified as the one in which the family therapy work is most clearly indicated.

The practice section gave the structure of the first session with the parents, the five components of a parent-focused intervention, the case for sequencing the parents first with its empirical basis, the four

reasons the parents might not be able to do the work, the four elements of school consultation, and the interventions that can be delivered directly to the young person.

The case of Samuel demonstrated the chapter. The referral was about compliance; the sequence revealed an escape-maintained refusal produced by the mother's own repeated questions; the restriction broke the cycle; the work question was re-specified so that it could not be answered with "fine"; and the practitioner told the mother explicitly that the arguing would not stop and that the goal was a different relationship rather than the elimination of the disagreement.

The evidence was summarised with its limits, and the strengths and limitations were set out with the principal risk identified: that the approach will locate the problem in the parent when the problem is elsewhere. The ethical section took up the question of whose problem is being treated, with four categories and the corresponding interventions, and made the point that a practitioner who does not ask the fourth question will systematically misdiagnose the families who most need help. The cultural analysis addressed the specificity of the parenting constructs, the possibility that the "most effective" practices are the most damaging across cultures, the authoritative and authoritarian distinction, the under-involvement of fathers, and the adaptation of the materials. The ethical requirements closed the chapter with the prohibition on the use of the work to obtain compliance and the requirement of equity of access.

## 12. Review and Discussion Questions

**Review and Discussion Questions**

1. State the chapter's central argument and give the developmental reason for it.
2. State the four parent accountabilities in the adolescent years.
3. Explain the parental task of mourning the child, and the consequence of its omission.
4. Define the structural mismatch and state the clinical test for it.
5. State the three-part task of the practitioner and explain the first element.
6. Describe the escalation cycle and state its three features.
7. Summarise the parent training evidence, including the breadth of the effects.
8. State the six core skills of parent training.
9. Explain the caution about the behavioural model of parenting and state the resolution.
10. State the characteristics of the mainstream and the conflict communication patterns.
11. Describe the four phases of the disclosure process.
12. State the two clinical conclusions that follow from the disclosure research, and explain the harm of treating the decline in disclosure as a symptom.
13. Describe the three common conflicts and identify the one in which the family therapy work is most clearly indicated.
14. Describe the structure of the first session with the parents.
15. State the five components of a parent-focused intervention.
16. Explain the case for sequencing the parents first, with the empirical basis.
17. Describe the four situations in which the parents will not or cannot do the work, and the response to each.
18. State the four elements of school consultation.
19. State the interventions that can be delivered directly to the young person.
20. Describe the case of Samuel and state the three features of it that generalise.
21. Summarise the evidence for parent-focused work and state its five limitations.
22. State the six strengths and five limitations of parent-focused work.
23. State the four categories of "whose problem is being treated" and the intervention that follows from each.
24. Explain the four cultural considerations for parent-focused work.
25. State the six ethical requirements for this work.

## 13. Practice Activities

**Practice and Application**

### Activity 33.1 — Mapping the Escalation Cycle (75 minutes, field-based)

Take a real case from placement, or a relationship you are closely involved in, and map the escalation cycle on paper, in the specific terms in which it occurs, with the actual words that are used. Then mark the point at which the cycle would break if one person did something different, and write what that something different would be. Then write the sentence that would introduce that change to the family without it sounding like an accusation. The last step is the one that matters, and most students discover that the change is easy to specify and hard to introduce.

### Activity 33.2 — The Mainstream and Conflict Audit (60 minutes, individual)

Using the mainstream and conflict pattern lists from Section 3.1, rate a family you know on each of the twenty characteristics. Then write the three characteristics on which the family most clearly deviates from the mainstream, and for each, write the specific practice that would move it. The point of the exercise is the discipline of moving from a general impression to a specific behaviour, and of resisting the temptation to work on the twenty characteristics rather than on the three.

### Activity 33.3 — The Three-Year Question (60 minutes, triadic)

One student plays a parent who has referred their fifteen-year-old for "rude and lazy"; one plays the counsellor; one observes. The counsellor's task is to ask the question "What do you want for your daughter in three years' time?" and to follow it wherever the parent goes, without rescuing the parent from their own answer. The observer's task is to note the moment at which the parent's account of the problem changes, and to write down the exact wording at that moment. Almost every group finds that the parent's answer to the three-year question is not about compliance at all.

### Activity 33.4 — The Consultation Map (60 minutes, small group)

In groups of three, take a school-based case and draw a map of the behaviours at home and at school, with the specific antecedents and the specific consequences in each setting. Then identify the three places where the settings are giving contradictory messages to the young person, and write the specific conversation needed with the school. Then identify what the practitioner must ask the young person before the school conversation happens. The third step is the ethical step, and the groups consistently discover that the third step has been omitted in most of the cases they have known.

## 14. Annotated Reading Pathways

**For the developmental rationale.** Read Steinberg (2014) for the authoritative parenting account, Sroufe (1995) for the attachment foundation, and Smetana (1995) for the disclosure research. The disclosure research is the most clinically useful of the three and the most frequently unknown.

**For the intervention.** Read the Oregon model manual and Dishion and McDonough for the intervention science, and read a parent training curriculum in full. The curriculum is more useful than the research literature for practice.

**For the consultation.** Read the school-based family intervention literature, and read the consultation literature on aligning school and home. The alignment problem is the one that most often defeats an otherwise sound plan.

**For the ethics and culture.** Read the evidence on cross-cultural variation in parenting, read the literature on the use of parent training with families who do not share the practitioner's parenting norms, and read the

ethical guidance on the use of behavioural techniques with families.

**For the harder cases.** Read the family-based treatment literature for adolescent substance use and for eating disorders, and read the multisystemic therapy literature. These are the cases in which the parent-focused work needs to be embedded in a larger system, and they are the ones that most often present.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Family Therapy with Parents and Adolescents** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is developmental and systemic consultation with families in conflict. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is family patterns, attachment, boundaries, communication, stories, and relational resources. The mechanism to keep in view is how interaction sequences and shared meanings distribute distress, protection, responsibility, and possibility across a system. The characteristic professional risk is blaming families, exposing a young person in unsafe joint sessions, or ignoring material conditions and individual needs. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 7. Apply the method | Use the chapter's core procedures in family meetings, school consultations, care networks, and individual sessions informed by systems thinking, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support,

timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Leah is fifteen and is seen in a family support service for repeated classroom escalation. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Leah's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Leah explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on family patterns, attachment, boundaries, communication, stories, and relational resources. The first intervention is deliberately modest. Leah chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Leah has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Leah can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be

sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Family Therapy with Parents and Adolescents

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Family Therapy with Parents and Adolescents** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

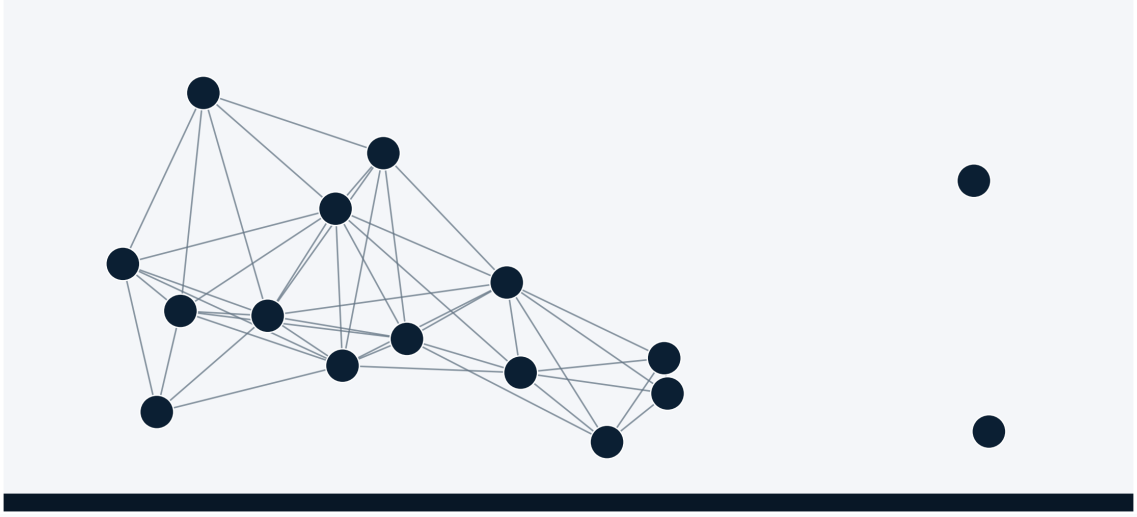
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Family Therapy with Parents and Adolescents** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Family Therapy with Parents and Adolescents**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into



clinical governance.

**Written consolidation.** In 250 words, explain Family Therapy with Parents and Adolescents to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 34

# Attachment Theory and Attachment-Based Therapy

Bowlby, Ainsworth, and the translation of attachment research into treatment.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain Bowlby's account of attachment, including the behavioural control systems, the function of attachment, and the conditions of its formation.
- Describe the research tradition that established the attachment patterns, including the strange situation and the Adult Attachment Interview.
- State the four attachment categories in children and the three in adults, and describe the developmental implications of each.
- Explain the construct of the internal working model and describe its developmental trajectory.
- Describe the principles of attachment-based therapy and its main variants, including the Child and Family Traumatic Stress Intervention and the dyadic developmental psychotherapy.
- Apply the attachment framework to a case involving a young person in a family with a history of loss or maltreatment.
- Critically evaluate the cultural and ethical dimensions of attachment-based work, including the questions of the cultural specificity of the attachment categories and the status of the caregiver's own attachment history.

## Chapter Overview

Attachment theory is the developmental foundation on which much of the practice of this book rests, and it is the theory with the most robust empirical base in the developmental sciences. It is also, in the form most practitioners encounter it, the theory that has been most simplified and most misused.

The theory's central claim is that attachment is a **behavioural system** — a set of evolved, functional, and biologically prepared systems that the infant uses to regulate affect, to explore, and to form a model of the world and of the availability of others. It is not, in the form in which it is often described, a claim about love, and it is not a claim about dependency, and the practitioner who treats it as either will be working with the wrong construct.

The claim that matters most for this book is that the attachment relationship is the organising context of the child's behaviour, and that the internal working model built from that relationship — the expectations about the availability of others, about their trustworthiness, and about the self as worthy or unworthy of care — is carried forward into the child's understanding of other people and of themselves. The adolescent who is unable to trust, who expects to be abandoned, who cannot accept comfort, and who believes that needing anyone is dangerous, is presenting a working model, and the working model was built somewhere.

The theory has also been the source of a serious scientific dispute, and the dispute should be known: the question of whether attachment patterns are categorical or dimensional, the question of the cross-cultural universality of the patterns, the question of the relationship between attachment and the individual-differences measures, and the question of whether the adult attachment interview measures the same construct as the strange situation. The discipline's handling of these disputes is itself a lesson in how a field should treat its own instruments.

# 1. Historical Context

## 1.1 From psychoanalysis to ethology

John Bowlby trained in psychoanalysis and was, for most of his career, in substantial opposition to the psychoanalytic tradition. His central objection was methodological: psychoanalysis proposed a set of developmental stages and a set of intrapsychic mechanisms that were, in his phrase, "unknowable" and therefore untestable, and the claim that the mother was the sole and exclusive object of the infant's attachment was, in his view, supported by evidence that was of a piece with the phrenology of the nineteenth century.

Bowlby's answer was to turn to ethology — the study of animal behaviour — and to look at the actual behaviour of mammals. What he found was a set of behavioural systems that were universal across the species and that had clear functions: **attachment**, which provided a safe base from which to explore and a refuge from threat; **feeding**, which was also the physiological system for the growth of the body; and **avoidance and exploration**, which constituted the other half of the human behavioural repertoire.

The functional argument was that the attachment system is **selected for** because of its consequences: infants attached to their mothers survived. The claim of the 1960s papers was that the attachment relationship was a **primary** system, a species-typical system present from birth, biologically prepared, and not a derivative of feeding.

## 1.2 The critical period and the monotropy hypothesis

Bowlby's developmental claims were the ones that caused the most controversy. He proposed a **critical period** in the first eighteen months to two years during which the attachment relationship is formed, and a **sensitive period** thereafter in which the relationship can still be formed but more rigidly. And he proposed **monotropy** — that the infant forms a single, primary, exclusive attachment, normally to the mother, and that other relationships are secondary.

The critical period claim was attacked on the grounds that it implied that separation after two years was catastrophic, and this was in turn attacked on the grounds of the effects of the orphanage studies of the 1940s and 1950s, which showed that children raised in institutions without a consistent caregiver developed profound difficulties. Bowlby's rejoinder was that the institution's failure was not the timing but the absence of a consistent figure, and the distinction matters.

## 1.3 The controversies

Three controversies dominated the field and all three are still live.

**The nature of the attachment categories.** Whether attachment is categorical — a small number of qualitatively distinct patterns, as in the strange situation — or dimensional — a continuum of scores, as in most of the self-report measures — remains unresolved, and the resolution is a matter of the measurement instrument rather than of the theory.

**The cross-cultural universality of the patterns.** The strange situation was developed in a specific social context, and its cross-cultural use produced a well-known problem: the pattern that looked "avoidant" in one setting was the pattern that looked "secure" in another, in which the caregiver's response to a stranger was appropriate. The resolution was the recognition that the strange situation measures the *child's* response to the reunion, and that the *caregiver's* response must be coded separately, and that the classification is of the

child, and that the categories do not have the same meaning in every setting. This is an important methodological lesson and it is directly relevant to the cultural analysis in Section 11.

**The relationship between the child and the adult measures.** The Adult Attachment Interview measures a quite different construct from the strange situation: it measures the discourse of an adult about their own attachment history, and the categories it produces (secure, preoccupied, dismissing, and the unresolved category) have a rather different meaning from the child's categories, and the correlation between the two is modest. Practitioners who treat the two as interchangeable are making an error.

### 1.4 The move to the clinic

Attachment research moved into clinical practice through several paths. The **attachment-based family therapy** developed by the Attachment and Biobehavioral Catch-up (ABC) group, and the **Child and Family Traumatic Stress Intervention (CFTSI)** of the same group, translated the research into parent-focused interventions for young children who have been maltreated. The **dyadic developmental psychotherapy (DDP)** of Linehan's group, described in Chapter 42 in relation to mentalization, translated the attachment findings into a treatment for young people with attachment disruption, including those with a borderline personality disorder. And the **Mentalization-Based Treatment** of Fonagy and Bateman, described in Chapter 42, was built on the attachment research and has become the most substantial evidence-based treatment for adolescent borderline personality disorder.

## 2. The Core Theory

### 2.1 Attachment as a behavioural system

**Attachment** is a behavioural system organised around the child, activated by the child's need for protection, and functioning to provide a secure base from which to explore and a refuge from threat. The system's functions are:

**Protection.** The attachment figure provides a refuge in the face of threat, and the child's proximity to the figure reduces the physiological arousal associated with threat.

**Proximity maintenance.** The system is activated by separation and by threat, and it produces the child's seeking of the figure.

**A secure base.** The system promotes exploration from the point of security, and the exploratory behaviour is more extensive and more effective when the secure base is available.

**An affect regulation system.** The child's capacity to manage negative affect is a function of the availability of the attachment figure, and the internalisation of that capacity over the first years is the developmental foundation of the regulation of affect throughout life.

**A basis for the self.** Bowlby and his colleagues proposed that the attachment relationship is the setting in which the sense of self is constructed, and the two are complementary: the child's model of the other as a reliable or an unreliable person and the child's model of the self as worthy or unworthy of care are developed together.

### 2.2 The conditions of attachment

Three conditions are necessary for the formation of an attachment, and all three are necessary and none is sufficient.

**Availability.** The caregiver must be available and responsive.

**Sensitivity.** The caregiver must be sensitive to the child's signals, and the sensitivity must be accurate rather than perfect, because a caregiver who responds to every signal in a synchronised way produces a child with no capacity to manage the states that arise when the caregiver is unavailable.

**Affective investment.** The caregiver must be affectively invested in the child, and the child must be able to recognise that the caregiver is invested in them.

The three conditions can be separated empirically, and the separation is clinically important. A caregiver can be available and insensitive; a caregiver can be sensitive and not invested; a caregiver can be invested and unavailable. Each produces a different pattern, and each requires a different intervention.

### 2.3 Attachment and the other behavioural systems

Attachment operates in relation to the other systems and is not the only influence on behaviour.

**The exploratory system** is inhibited by attachment activation, and the child who is constantly anxious will not explore, and the exploration deficit is a common presentation.

**The caregiving system** is activated by the young person's cues and is suppressed by the young person's anger and by the caregiver's own unresolved loss. A parent whose own attachment history is unresolved may be unable to provide the caregiving that the young person cues for, and the young person's angry protest is exactly the signal that suppresses the caregiving system.

**The sexual system** develops through puberty and is not a derivative of the attachment system, and its interaction with the attachment system in adolescence produces the specific difficulties of the sexuality conflict described in Chapter 33.

## 3. The Internal Working Model

### 3.1 The construct

The **internal working model** is the set of expectations, drawn from the primary relationship, about the availability and the trustworthiness of others, about the response of others to one's own needs, and about the worthiness of the self. It is a cognitive schema that operates largely outside awareness, and it is both an interpreter of new experience and a generator of behaviour.

The three components are as follows.

**A model of the attachment figure** — as available or unavailable, as responsive or unresponsive, as trustworthy or not.

**A model of the self** — as worthy of care or not, as able to elicit care or not, as having a right to need or not.

**A model of the interaction** — whether the seeking of comfort works, whether the protest produces response, and what happens when the figure is unavailable.

### 3.2 The developmental trajectory

The working model is built in the first two to three years, and it is then **revised** rather than replaced.

**From birth to three years**, the model is built from the primary relationship. It is a relatively simple, affective, and non-verbal schema, and it is formed by the repeated experience of the infant's signals being answered.

**From three to six years**, the model is elaborated. The child can now hold a mental representation of the caregiver, can anticipate responses, can begin to use it to plan behaviour, and can develop the fantasy and the reality as separate systems.

**From six to eleven years**, the model becomes increasingly deliberate and increasingly capable of being reflected upon, and the child can be argued with, and this is a direct consequence of the cognitive development of the period.

**From eleven onwards**, the model becomes a more organised and more differentiated system, capable of multiple relationships, of ambivalence, and of reflection, and the adolescent's task is the *revision* of the model rather than its formation, and the revision is what the developmental literature calls the *secondary revision* of the working model.

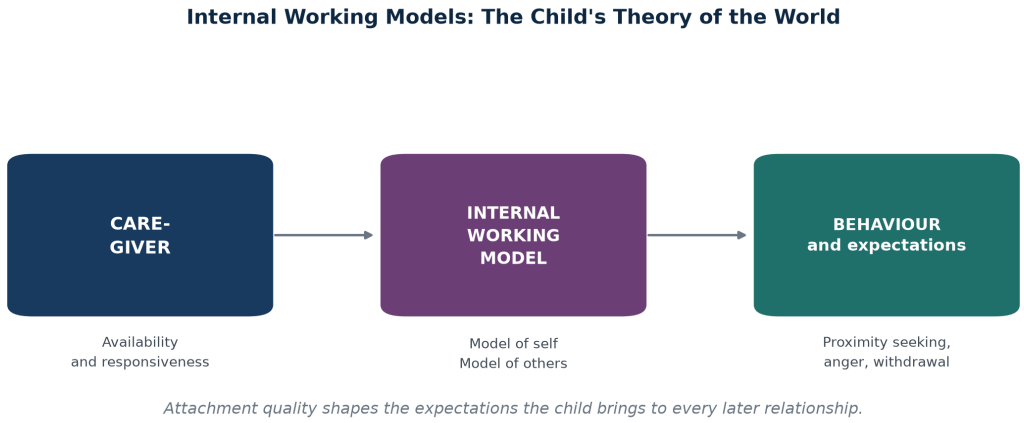


**Figure 34.23** The internal working model represented as a schema with three components — a model of the attachment figure, a model of the self, and a model of the interaction — and the developmental revisions that occur across the life span.

## 3.3 The revision in adolescence

Two processes operate in adolescence and both are clinically important.

**The revision of the working model.** The adolescent's developmental task includes moving from the primary relationship to a wider world of relationships, and this requires a revision of the working model that permits multiple relationships of different kinds. The adolescent who has a working model in which all relationships are of the same kind and carry the same expectations cannot make the move, and the young person who remains in a pattern of intense and exclusive relationships is often presenting this.

**The acquisition of the capacity to sustain a relationship through a period of developmental change.** The working model of the childhood is a model of a relationship in which the other is stable. The adolescent's relationships are with people who are also changing, and the working model must be revised to accommodate the mutability of the other.

The clinical relevance is that an adolescent with an insecure working model will be at their most vulnerable precisely at the developmental point at which the working model is under revision, and a practitioner who interprets the adolescent's relationship difficulties as a regression is making a serious error.

# 4. The Attachment Patterns

## 4.1 The child categories

The categories derive from the **strange situation**, a laboratory procedure in which the child's behaviour is observed across a series of eight episodes in which the caregiver and a stranger are present or absent.

**Secure.** The child explores readily, is distressed on separation, is readily comforted on reunion, and is not markedly avoidant of the caregiver.

**Avoidant (insecure-avoidant).** The child does not distinguish between the caregiver and the stranger, explores readily even during separation, shows little distress at separation, and avoids the caregiver on reunion. The avoidant pattern is a defensive strategy: the child's experience of the caregiver's availability is unpredictable or the caregiver's responses are rejecting, and the child has learned that the reliable response to needing is to not need.

**Ambivalent or resistant (insecure-ambivalent).** The child is preoccupied with the caregiver, explores little, is highly distressed at separation, is angry on reunion, and is difficult to comfort. The ambivalent pattern reflects a history of caregiver behaviour that is unpredictable and inconsistently responsive, so that the child is angry about the separation and is also unable to use the caregiver on reunion.

**Disorganized.** The child shows contradictory, frozen, or dazed behaviour in the caregiver's presence, and the behaviour of the caregiver is the key to understanding it. The disorganized pattern is the one associated with maltreatment and with the loss of a caregiver, and it is described in the clinical literature as a **fright without solution**: the child approaches a caregiver who frightens the child, and the child has no organised strategy for this.

## 4.2 The adult categories

The adult categories derive from the **Adult Attachment Interview**, which is a semi-structured interview about the adult's own childhood and its significance, and which is scored for the quality of the discourse rather than for its content. The categories are:

**Secure (autonomous).** The narrative is coherent, the account of the difficulties is not accompanied by a defensive dismissal, and the person can describe the effects of their history without being overwhelmed.

**Preoccupied (anxious).** The narrative is detailed and often vivid, and the account of the past is marked by unresolved conflict, by a sense of the parent's own needs intruding, and by a difficulty in moving on from the past.

**Dismissing.** The account is minimised, the difficulties are attributed to the child or to the circumstances, and the person presents as self-sufficient and uninterested in the discussion.

**Unresolved (or preoccupied/unresolved).** The discourse shows lapses in monitoring, disorganised or contradictory accounts, and unusual responses to the losses in the person's history, and this category is associated with unresolved grief and with trauma.

The critical point for the practitioner is that these categories are *not* the adult versions of the child's categories, that they are derived from a different instrument measuring a different construct, and that the two are only modestly correlated.

### 4.3 The attachment matrix

A useful clinical instrument combines the two: the **attachment matrix** plots the young person's behaviour in the session against the attachment signals the practitioner observes in the caregiver, and the two are read against each other.

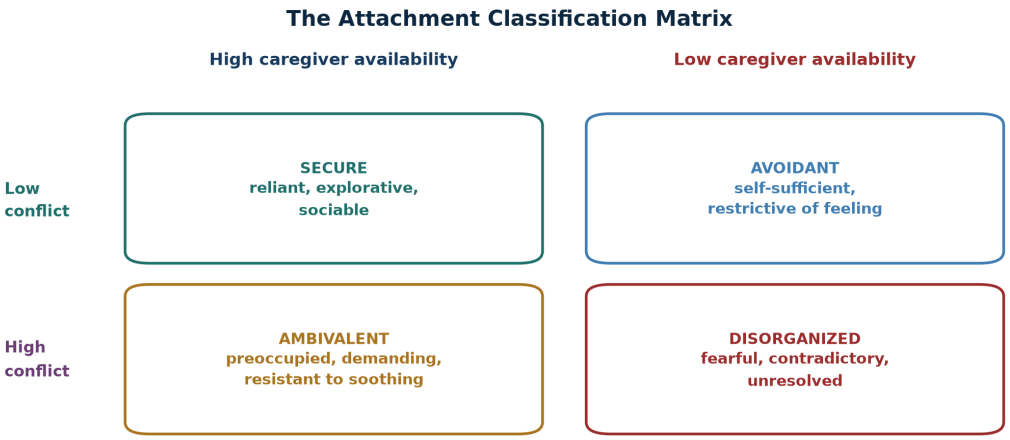

**Figure 34.24** The attachment matrix, plotting the young person's behaviour in the session against the attachment signals shown by the caregiver, with the four quadrants labelled.

The reading is as follows. A young person who is **avoidant in the session** with a caregiver who is **preoccupied** is a young person who has learned to manage the caregiver's anxiety, and the intervention is with the caregiver. A young person who is **preoccupied** with an **avoidant** caregiver is a young person whose bid is being met by withdrawal, and the intervention is to introduce a consistent and responsive source of care, which is frequently a professional. A young person who is **disorganised** with a caregiver who is **unresolved** is the classic maltreatment presentation, and the intervention is the most difficult in the field.

## 5. Attachment-Based Therapy

### 5.1 The principles

The attachment-based therapies share five principles, and a student should be able to state them.

**The relationship is the treatment.** The therapy is directed at the development of a relationship in which the young person can experience the caregiver as available and responsive, and the therapeutic relationship itself is the vehicle through which the working model is revised.

**The caregiver is the target of the intervention.** The work is with the caregiver's responsiveness, because the young person's working model is built from the primary relationship, and a change in the caregiver's availability is a change in the material from which the model is built.

**The developmental task is respected.** The work does not treat the young person's behaviour as a problem to be extinguished but as an attempt to manage a situation that has been overwhelming, and the developmental appropriateness of the intervention is the requirement.

**The intervention is the creation of conditions in which the attachment system can be used.** In practice this means the removal of the conditions that suppress the attachment system — the anger that suppresses the caregiving system, the inconsistent response that teaches the child to manage the caregiver's anxiety, the maternal behaviour that teaches the child to self-soothe.

**The treatment of the caregiver's own attachment history is a component.** A parent with an unresolved attachment history will reproduce the pattern, and the work with the parent's history is part of the work with the child.

## 5.2 The variants

**Attachment and Biobehavioral Catch-up (ABC)** is a parent-mediated intervention for infants and toddlers who have experienced maltreatment or disrupted caregiving. The core procedure is the video-feedback intervention: the parent is filmed interacting with the child and then watches the recording with the practitioner, who helps the parent to see the child's bids and their own responses. The evidence base is good, and the mechanism is understood.

**Child and Family Traumatic Stress Intervention (CFTSI)** extends the ABC work to the treatment of trauma in children aged three to six and to their caregivers, combining the video-feedback with the teaching of specific skills: the recognition of the child's trauma-related behaviour, the reduction of the child's avoidance, the parent's own regulation, and the development of the child's attachment behaviours.

**Dyadic developmental psychotherapy (DDP)** is a parent-child attachment intervention for young people with attachment trauma and for those with emerging or established borderline personality disorder. Its distinguishing feature is the **PACE** stance — Playfulness, Acceptance, Curiosity, and Empathy — and its technique is the "follow your lead" responsive interaction in which the practitioner enters the child's world and reflects back the child's own intentions with delight. The evidence base is good and it is the most substantial of the attachment-based treatments for the adolescent population.

**Mentalization-Based Treatment** is described in Chapter 42 and is the largest evidence base of all the attachment-based approaches for adolescent borderline personality disorder.

**The general principles applied without a protocol** — the practitioner working with the caregiver's responsiveness, with the recognition of the young person's bids, with the repair of ruptures, and with the parent's own history — are the practice that most practitioners in this book will actually need, and they are what the rest of this chapter describes.

## 5.3 The practices

**The recognition of the bid.** A bid is a small, usually nonverbal, signal that the young person is seeking proximity, contact, or reassurance. The practitioner's task in the first sessions is to learn to see them, and the technique is the same as the technique used in the ABC video-feedback: the practitioner observes, names

what the young person did, and names what it meant.

**The response.** The response must be prompt, and it must be congruent, and it must be about the bid and not about the behaviour. A young person who is angry at being told what to do is not making a bid and should not be responded to as one.

**The repair.** The most important single practice. When the practitioner misses a bid — and the practitioner will, and the young person will know — the repair is the opportunity. The practitioner names what happened, acknowledges the young person's response, and does not require the young person to reassure them. A practitioner who can repair a rupture with a sixteen-year-old has demonstrated more than a practitioner who has never missed one.

**The prohibition on the use of the therapeutic relationship to produce compliance.** This is a critical ethical point in the attachment-based work and it is stated explicitly in the CFTSI and the DDP protocols: the practitioner does not use the attachment relationship to secure the young person's cooperation, and the practitioner does not withhold to secure it. The attachment figure must be available precisely when it is not needed for the practitioner's purposes.

**The consistency of the response.** The response must be the same every time, and the "every time" includes the times when the practitioner is tired, and this is why the work is best done in a team.

**The work with the caregiver's history.** The parent's unresolved grief, the parent's own experience of being cared for or not, and the parent's own unresolved losses are worked with, usually in a separate strand, and the practitioner should expect that a parent whose own history is unresolved will struggle to respond consistently.

# 7. Attachment-Based Work with Children and Adolescents

## 7.1 The developmental fit

Attachment theory is unusually well matched to the adolescent period, and the reasons are worth stating precisely.

**Adolescence is the period of the working model's revision.** The adolescent's developmental task includes the revision of the expectations about others that were formed in the first three years, and the revision is possible only in the context of a relationship that is safe enough to revise in.

**Adolescence is the period of the secondary attachment systems.** The peer relationships, the teacher relationships, and the relationships with non-parental adults become the significant developmental relationships, and the adolescent's working model is revised in the context of these.

**The attachment system is at its most activatable in adolescence.** The hormonal and social changes of the period increase the salience of attachment cues, and the adolescent who is in an insecure state is at the point at which the system is most easily reorganised and also most easily overwhelmed.

**The developmental task of separating from the parents is an attachment task.** The detachment from parental control described in Chapter 33 is the developmental renegotiation of the attachment relationship, and it is easier where the working model is secure, because a secure working model permits the adolescent to be autonomous without losing the relationship.

## 7.2 The presentations

Four presentations are common in adolescent attachment work, and the practitioner should be able to recognise each.

**The preoccupied adolescent.** The young person is intensely involved with the parents and with the practitioner, is anxious at separation, is angry on reunion, and is unable to tolerate the distance that the work requires. The underlying model is that the other is available but unreliable and that needing produces anxiety, and the intervention is the consistency of the response, and the introduction of a source of care that does not withdraw.

**The dismissing adolescent.** The young person is self-sufficient, deflects, does not seek help, describes the parents as fine and their own difficulties as nobody's business, and is subtly contemptuous of emotional display. The underlying model is that needing is dangerous and that the self is worthless as a source of comfort, and the intervention is the repeated, patient demonstration that the need will be met, which takes a long time and requires the practitioner to be willing to be unhelpful in order to be reliable.

**The disorganised adolescent.** The young person's behaviour in the session is contradictory: she approaches and then withdraws, or is simultaneously warm and hostile, or is dissociate and present at the same time. The underlying pattern is the absence of an organised strategy, and the clinical significance is that the young person's behaviour cannot be interpreted as communication, and the practitioner must not try.

**The young person with no stable attachment figure.** The young person has had a series of caregivers and has no figure to whom the attachment system is directed, and the system is consequently unattached and is available for attachment to a new figure. This is the young person for whom the therapeutic relationship may be the first secure base, and it is also the young person for whom the abandonment of the therapeutic relationship will be most damaging, and the termination planning of Chapter 58 is correspondingly important.

## 7.3 Working with the caregiver

The work with the caregiver has five components, and they are the substance of the attachment-based practice.

**The observation of the interaction.** The practitioner watches the young person and the caregiver together, and the practitioner's task is to see the bids and the responses. This is the technique of the ABC video-feedback and it is the technique of the observation in the DDP model, and it is learnable.

**The naming of the bids.** The practitioner names, in the session, what the young person did and what it meant: "she moved her chair closer to you three times in the last ten minutes, and each time she did it she also looked at the door." The naming is done with the caregiver, in a way that is observational rather than evaluative, and the shift from "she is attention-seeking" to "she is seeking you and checking whether you are available" is the single most useful clinical move in the work.

**The consistency of the response.** The caregiver is helped to respond promptly and congruently, and the specific guidance is given about the two common failures: the response that is delayed and the response that is inconsistent.

**The repair.** The caregiver is taught to repair ruptures with the young person, and the repair is demonstrated and rehearsed, because most caregivers have never repaired a rupture with their own parent and do not know that it is possible.

**The caregiver's own history.** Where the caregiver has an unresolved history, the work on it is a component, and it may need to be referred to a clinician who can work with an adult's attachment history, because it is a different set of skills from those of the adolescent work.

### 7.4 The young person's developmental work

**The recognition of the need.** Much of the work with the insecure adolescent consists of helping the young person to notice their own bids, which is a considerable achievement for a young person who has learned that bids are met with rejection or with withdrawal.

**The tolerance of the need.** The young person must also learn to tolerate the need — to sit with the discomfort of needing, without immediately doing something to end it. This is the developmental work of the secure base.

**The testing.** The young person will test the practitioner, and the tests will look like provocation or sabotage. The tests are of the same kind as the tests of the infant, and the practitioner's task is to respond in a way that is congruent and non-defensive, and to notice afterwards what the test was for.

**The multiple relationships.** The developmental task of moving from the primary relationship to a wider world of relationships is supported concretely: the young person is helped to find and to sustain other relationships, in the peer world, with other adults, and the practitioner supports rather than blocks this.

### 7.5 The relationship with the practitioner

The ethical and clinical requirements of the attachment relationship with the practitioner are strict, and a student should be able to state them.

**The practitioner is available and consistent.** This is the basic requirement, and it is the hardest to provide in a service with short contacts and high turnover, and the services with the highest turnover are the ones with the most attachment-disrupted young people.

**The practitioner does not withhold.** The practitioner does not use the relationship to secure compliance, and does not withdraw to produce a change, and does not withhold to teach a lesson.

**The practitioner does not require reassurance.** The young person is not required to reassure the practitioner, and the practitioner does not ask for it, and the asking is a common error in inexperienced practitioners.

**The practitioner repairs.** The practitioner names the rupture and does not require the young person to repair it.

**The practitioner is honest about the limits.** The practitioner tells the young person about the end of the therapy, about the limits of their availability, and about what will happen if the young person is in crisis. The honesty is itself an attachment experience, and it is different from the experience of a practitioner who is reliable in the sessions and absent in the crisis.

## 8. Case Illustration: The Young Woman Who Had Learnt to Be Left

**Presentation.** Nadia is sixteen and has been placed in foster care for the second time in two years. She is referred by the school with "attachment difficulties, refuses to engage, and has already said she will not be here long." The placement is with a family she has met twice.

**The first session.** Nadia is late, and she is polite, and she is careful, and the practitioner notices the following things and writes them down. Nadia asks, in the first five minutes, how long the sessions are. She asks whether the practitioner will be there next week. She says, in the middle of the session, "I don't really

do the talking thing, you should know that now." And she does not, at any point in fifty minutes, refer to anything that has happened to her.

The practitioner also observes Nadia's body, because the practitioner was trained to observe bodies, and Nadia's shoulders are raised and her voice is pitched slightly high and her hands are busy with the sleeve of her jumper throughout the session.

**The attachment matrix.** In the first family session, the matrix is read. Nadia is **dismissing** in the session: she does not seek the foster parents, does not look at them, answers their questions briefly, and presents as a young woman with no needs. The foster mother is **preoccupied**: she talks a great deal, she explains the house rules, she asks Nadia repeatedly how she is settling, she says "we just want you to feel at home", and she is visibly hurt by Nadia's flatness. And the practitioner observes the pattern in the room: the foster mother asks a question, Nadia gives a minimal answer, the foster mother asks again, and the second question is more emotional, and Nadia becomes more closed.

The matrix reading is: **the young person is managing the adults' anxiety, and she is doing it by being self-sufficient.** The foster mother's anxiety produces the second question, the second question produces the withdrawal, and the withdrawal produces the foster mother's hurt, and the hurt produces more checking. Nothing in the system is a behaviour problem. Everything in the system is the attachment system in operation, in a young person who learned in her first fourteen years that the reliable response to an adult who is anxious is to stop needing anything.

**The formulation.** The working model, as the practitioner reconstructs it from the school records, the previous placement's notes, and Nadia's own fragmentary account, contains a model of the other as unavailable and a model of the self as not worth the trouble. The specific history is not yet known and the practitioner does not invent it; the first task is to establish it, carefully, over time, and at Nadia's pace.

**The intervention.** Five elements.

*Element one: the foster parents' preparation.* Before the second session, the practitioner meets the foster parents alone and explains the attachment matrix reading in plain terms: "Nadia is not being cold. She is being careful. And the reason she seems cold is that she has learned that when adults worry, they ask again, and when they ask again, they get upset, and when they get upset she ends up having to manage their feelings." The practitioner tells them what the work will require: consistency, patience, a small number of bids being answered, and a great deal of repetition before anything changes. The foster mother cries at this point, and the practitioner does not interpret the crying, and this is itself a demonstration of the practice.

*Element two: the change in the foster parents' responding.* The specific instruction is: "Ask once. If she answers, that is the end of the question. If she says nothing, that is also the end of the question. And then, in the evening, tell her one thing you noticed about her that is not about school or about the house rules — that she ate all of the lasagne, that she was reading on the sofa, that she laughed at something — and then stop talking." The purpose of the evening message is to establish that the contact continues when the young person has not initiated it, without the young person having to do anything to end it.

*Element three: the placement question.* The practitioner addresses the placement's framing directly. The statement in the school referral that Nadia "will not be here long" is a prediction, and the prediction is a self-fulfilling one, and the practitioner says so to the team: "If we expect her to leave, we will read everything she does as evidence that she is leaving, and she will pick that up in about a week." The team agrees to a review at three months rather than at six weeks.

*Element four: the individual work.* The work with Nadia is slow and consists of three things. First, the practitioner is boring and reliable: the same time, the same room, the same ten minutes of talking about nothing at the start. Second, the practitioner names the bids when they occur, gently and without pressure: "You asked me twice whether I would be here next week." Third, the practitioner does not require any disclosure. The practitioner explicitly says: "You do not have to tell me anything about what has happened. That is not what this is for. What I am for is being here."

*Element five: the developmental work.* Two pieces. The first is the finding of an adult outside the family: a youth worker at the school, a specific and reliable person, and the practitioner introduces them and then steps back. The second is the introduction of the peer world, which Nadia has given up entirely, and the work is to get one, low-demand social activity — a youth group, a sports session, a shift at the school café — with the specific and deliberate aim of giving her a relationship with a peer that is not a performance.

**The outcome.** At three months Nadia has not disclosed anything about her history, and the practitioner regards this as a good outcome and says so to the team. She has stopped asking whether the practitioner will be there. She has come to three of the youth group sessions and has spoken to two of the other young people. The foster mother reports that "she's still not affectionate but she comes down for dinner now, and she told me about a song."

**The interpretation.** The case illustrates the attachment framework in practice and it makes two points that a student should take away. The first is that the young person's "refusal to engage" was a competent and adaptive response to a history in which engaging was dangerous, and the label was describing the coping and calling it the pathology. The second is that the most important clinical event in the three months was not a disclosure and was not a breakthrough; it was the provision of a predictable adult and the removal of the double question, and the durable change in a young person with a disrupted attachment history is built out of exactly that.

# 9. Evidence and Research Support

## 9.1 The status of the evidence

Attachment theory has a large and rigorous research base, and the evidence for the interventions derived from it is good but narrower than the theory.

**The attachment research is highly reliable.** The strange situation and the Adult Attachment Interview are among the best-validated measures in the developmental sciences, with high inter-rater reliability, extensive normative data, and a large body of longitudinal research. The prediction of attachment classification into adulthood is among the more robust findings in the field.

**The longitudinal findings are strong.** Attachment classification in infancy predicts a range of outcomes at adolescence and in adulthood, with the largest effects in the socially and emotionally at-risk groups, and the effects are largest for the insecure classifications.

**The ABC intervention has good support** for infants and toddlers, and the video-feedback mechanism is understood.

**The CFTSI has good support** for young children with trauma and for their caregivers.

**The DDP has good support**, with a randomised controlled trial showing significant reductions in self-harm in the borderline population, and a body of mechanistic work on the PACE stance and on the development

of the mentalizing capacity.

**Mentalization-based treatment has the strongest evidence base** of all the attachment-based approaches for adolescent borderline personality disorder, and Chapter 42 develops it.

**The evidence for attachment-based work with the broader adolescent population is thin.** This is the honest position: a young person with an insecure attachment pattern and no diagnosed disorder is unlikely to be referred to an attachment-based treatment, because the presentation is not severe enough, and the evidence for the general application of attachment principles to adolescent presentations is limited to the clinical trials of the specific protocols.

### 9.2 Limitations of the evidence

**The measures are Western and the categories may not transfer.** The cross-cultural literature is substantial and the most serious methodological finding is the context-dependence of the caregiver's behaviour in the strange situation, and the field's resolution of it is partial.

**The adult and the child measures are not the same construct**, and the moderate correlation between the two has been over-interpreted in the clinical literature.

**Attachment classification is a group-level description**, and the predictive power at the level of the individual is considerably weaker than the group-level figures suggest, and this is a point of statistical sophistication that is important for a practitioner who is being told that a young person's category predicts their future.

**The intervention research is concentrated in infancy and early childhood** and in the borderline population, and the adolescent range is comparatively under-researched.

**The outcomes measured are largely behavioural and attachment-related**, and the mental health and the quality of life outcomes of the attachment-based interventions are less extensively reported.

## 10. Strengths and Limitations of the Attachment Perspective

### 10.1 Strengths

**It is developmentally founded and empirically supported.** The theory is not a metaphor and its measures are among the best in the field.

**It explains why the same young person behaves differently with different adults**, which is one of the most practically useful things a theory can do for a practitioner.

**It provides a formulation of the young person as adaptive**, which is both more accurate and more useful than a formulation of the young person as defective.

**It is practical.** The bids, the responses, the consistency, and the repair are learnable and they are usable in any modality.

**It locates the target in the relationship**, which is where the developmental evidence points.

### 10.2 Limitations

**It under-accounts for the individual.** A young person with a neurodevelopmental condition, with a psychotic illness, or with a specific learning difficulty has difficulties that the attachment account does not explain.

**The categories are Western and their universality is contested**, and the practitioner who applies them cross-culturally without adjustment will misdescribe.

**The adult categories are frequently misapplied to young people**, and the adult attachment interview categories do not translate into the child categories.

**The relationship between attachment and the individual-differences measures is weaker than the clinical literature implies**, and the attachment story has sometimes been used to explain more than it can.

**The interventions are demanding.** The DDP requires a trained team and a stable placement, and the CFTSI requires trained parents and a video-feedback setup, and the services in which the young people who most need this work are found are frequently not resourced for it.

# 11. Cultural and Ethical Considerations

## 11.1 The cultural specificity of the attachment categories

The cross-cultural literature on attachment is one of the most methodologically instructive in the developmental sciences, and a student should know its central finding.

**The strange situation is not culturally neutral.** It was developed in a specific social context, and the classification depends on the cultural meaning of the stranger's behaviour and on the caregiver's familiarity with the procedure.

**The caregiver's response must be coded separately.** The most important methodological correction was to recognise that the strange situation measures the child's response to the reunion and that the caregiver's response must be coded independently, and that a caregiver's response that is coded as "insecure" in one setting may be coded as "secure" in another, because the meaning of the behaviour differs.

**The distributions differ across cultures.** Some studies have found higher proportions of the insecure classifications in certain settings, and the interpretation of these differences is contested, and the field's position is that the differences may reflect the circumstances of caregiving in those settings — the instability of the caregiving arrangements, the pressure on the caregiver, the absence of supports — rather than a deficiency in the caregivers.

**The categories may be a poor fit where caregiving is collective.** Where the primary caregiving figure is a kin network rather than an individual, the strange situation's assumptions about the singular attachment figure and about the exclusive relationship do not hold, and a practitioner who applies the categories will misdescribe the family.

**Practices that are optimal for attachment are not universally optimal.** The practices that produce a secure attachment — the consistent and sensitive response, the reliable caregiver, the stable routine — are good things in most circumstances, and in a setting where the family is under severe pressure they are additional demands on a caregiver who is already overwhelmed, and the clinical judgement required is to support the caregiver's capacity before expecting the practice of it.

## 11.2 Ethical considerations

**The therapeutic relationship as an attachment relationship.** The ethical status of the attachment relationship with the practitioner is a live question. The attachment-based approach treats the relationship as the treatment, which is powerful and which raises a question about the nature of the obligation when the relationship ends. A practitioner who has been the young person's secure base has a duty of care in the ending that goes beyond the ordinary termination, and the practice of the attachment-based approaches is to prepare for the ending from the beginning.

**The prohibition on the use of the relationship to secure compliance.** This is stated explicitly in the protocols and it is a genuinely different ethical position from the one in the behavioural tradition, and the two traditions can be in direct conflict in a case. A practitioner working with the behavioural approach of Chapter 26 and the attachment approach of this chapter must resolve the conflict explicitly, and the resolution will usually be that the attachment relationship is not to be used to produce the behaviour change, and that the behaviour change is not to be produced at the cost of the relationship.

**The status of the caregiver in placements.** A young person in a placement has a legal guardian who is not the attachment figure, and the conflict between the guardian's authority and the attachment relationship is a real and frequently mishandled difficulty.

**The young person's right to refuse.** The attachment approach must not become a means of compelling disclosure. A young person who declines to talk about her history has the right to do so, and the practitioner who pursues disclosure as a condition of the work has turned the secure base into a condition.

**Cultural and religious considerations in the caregiver's response.** The practices that the attachment literature recommends may conflict with a family's religious or cultural practices, and the practitioner should establish what those practices are before the intervention, and should not require the family to abandon them.

**Confidentiality and the caregiver's access.** The attachment-based approach requires the practitioner to share observations with the caregiver, and this must be negotiated explicitly with the young person.

**The avoidance of re-traumatisation.** The work with a young person with a disrupted history must not require the young person to revisit the history in order to prove that they have worked, and the practitioner must be prepared for the young person's own decision about how much to disclose, including the decision to disclose nothing.

## 12. Key Terms

### Key Terms at a Glance

- **Attachment** — A behavioural system organised around the child, activated by the need for protection, and functioning to provide a secure base for exploration and a refuge from threat.
- **The functions of the attachment system** — Protection, proximity maintenance, a secure base for exploration, affect regulation, and the basis for the self.
- **The behavioural control systems** — Attachment, feeding, and avoidance and exploration, each with its own functions and its own interaction with the others.
- **The three conditions of attachment** — Availability, sensitivity, and affective investment; all necessary and none sufficient.
- **Sensitivity** — The caregiver's accurate responsiveness to the child's signals, as distinct from a perfectly synchronised responsiveness, which produces a child with no capacity to manage the states that arise when the caregiver is unavailable.
- **Affective investment** — The caregiver's emotional investment in the child, and the child's recognition of it.
- **The critical period** — The period in the first eighteen months to two years during which the attachment relationship is formed.
- **The sensitive period** — The period after the critical period in which attachment can still be formed, but more rigidly.
- **Monotropy** — Bowlby's proposal that the infant forms a single, primary attachment and that other relationships are secondary.
- **The secure base** — The function of the attachment figure as the platform from which the child explores and to which the child returns.
- **Internal working model** — The set of expectations drawn from the primary relationship about the availability of others, about the response to one's needs, and about the worthiness of the self.
- **The three components of the working model** — A model of the attachment figure, a model of the self, and a model of the interaction.
- **The developmental trajectory of the working model** — Formation in the first three years, elaboration to six, deliberate reflection from six to eleven, and organised differentiation from eleven onwards.
- **The secondary revision of the working model** — The adolescent's revision of the working model, permitting multiple relationships of different kinds and mutability in the other.
- **Strange situation** — The laboratory procedure developed by Ainsworth and colleagues, consisting of eight episodes in which the caregiver and a stranger are present or absent.

### Key Terms at a Glance (continued)

- **Secure attachment** — The child who explores readily, is distressed on separation, is readily comforted on reunion, and does not avoid the caregiver.
- **Insecure-avoidant attachment** — The child who does not distinguish the caregiver from the stranger, shows little separation distress, and avoids the caregiver on reunion; a defensive strategy against unreliable availability.
- **Insecure-ambivalent attachment** — The child who is preoccupied with the caregiver, explores little, is highly distressed at separation, and is angry on reunion.
- **Disorganized attachment** — The contradictory, frozen, or dazed behaviour in the presence of a caregiver whose behaviour is frightening or whose history is unresolved; the "fright without solution".
- **Adult Attachment Interview** — The semi-structured interview about the adult's own childhood, scored for the quality of the discourse and producing the adult attachment categories.
- **Secure, preoccupied, dismissing, and unresolved** — The four adult attachment categories, derived from a different instrument from the child categories and only modestly correlated with them.
- **The attachment matrix** — A clinical instrument plotting the young person's behaviour in the session against the caregiver's attachment signals, read in four quadrants.
- **Attachment-based family therapy (ABC)** — The parent-mediated intervention for infants and toddlers, using video-feedback to teach the caregiver to see the child's bids.
- **Child and Family Traumatic Stress Intervention (CFTSI)** — The extension of the ABC work to the treatment of trauma in young children aged three to six and to their caregivers.
- **Dyadic developmental psychotherapy (DDP)** — The parent-child attachment intervention for attachment trauma and for emerging or established borderline personality disorder.
- **PACE** — The stance of playfulness, acceptance, curiosity, and empathy from which the dyadic developmental psychotherapy is delivered.
- **Follow your lead** — The responsive interaction technique in which the practitioner enters the young person's world and reflects back their intentions with delight.
- **The recognition of the bid** — The practice of noticing and naming the small signals by which a young person seeks proximity, contact, or reassurance.
- **Repair** — The practice of naming a rupture in the relationship and taking responsibility for it, without requiring the young person to reassure the practitioner.

**Key Terms at a Glance (continued)**

- **The prohibition on withholding** — The requirement that the attachment figure be available precisely when their availability is not needed for the practitioner's purposes.
- **The preoccupation with the small** — The developmental tendency of the adolescent period that makes the attachment system both more activatable and more reorganisable.
- **The four adolescent attachment presentations** — The preoccupied, the dismissing, the disorganised, and the young person with no stable attachment figure.
- **Attachment and the school context** — The application of the attachment principles to the school relationship, the classroom, and the school-based support.

## 13. Chapter Summary

Attachment theory is the developmental foundation of much of this book's practice, and its central claim is that attachment is a behavioural system with four functions: protection, proximity maintenance, a secure base, and affect regulation, and with the basis for the self as its developmental product. The chapter traced the history from Bowlby's break with psychoanalysis through the ethological argument, the critical period and monotropy proposals, and the three controversies that remain live — the categorical versus dimensional question, the cross-cultural universality of the categories, and the relation between the child and the adult measures.

The three conditions of attachment were described and their separability was noted, because the three failures produce three different presentations and require three different interventions. The internal working model was described in its three components and its developmental trajectory, with the adolescent's revision of the model identified as the developmental task of the period and the clinical error of interpreting the adolescent's relationship difficulties as a regression.

The attachment patterns were described in both the child and the adult categories, with the warning that the two derive from different instruments measuring different constructs and are only modestly correlated. The attachment matrix was described as a practical clinical instrument, with the four quadrants read and their interventions given.

The five principles of attachment-based therapy were stated, the five main variants were described with their evidence, and the five core practices were set out: the recognition of the bid, the response, the repair, the prohibition on the use of the therapeutic relationship to produce compliance, the consistency of the response, and the work with the caregiver's own history.

The work with young people was developed through the developmental fit, the four presentations, the five components of the work with the caregiver, the developmental work with the young person, and the strict requirements of the relationship with the practitioner, including the prohibition on requiring reassurance and the honesty about the limits of the availability.

The case of Nadia demonstrated the whole framework. The referral's "refusal to engage" was read, on the attachment matrix, as a young person managing the adults' anxiety by being self-sufficient, and the double question in the foster home was identified as the mechanism. The intervention was the preparation of the

foster parents, the change in their responding, the challenge to the placement's self-fulfilling prediction, the slow individual work that did not require disclosure, and the developmental work of finding an adult outside the family and a peer world. The outcome at three months was no disclosure and the practitioner treating that as a good outcome.

The evidence was presented with its structure: the attachment research is highly reliable and longitudinal, the intervention evidence is good but concentrated in infancy and in the borderline population, and the evidence for the general application of attachment principles to the adolescent range is thin. The limitations were named, including the statistical point that the prediction at the individual level is considerably weaker than the group-level figures suggest.

The cultural section addressed the cultural specificity of the categories, the context-dependence of the strange situation, the different distributions across cultures, the poor fit where caregiving is collective, and the point that the practices that are optimal for attachment are not universally optimal and may be additional demands on a caregiver who is already overwhelmed. The ethical section addressed the ethical status of the attachment relationship and the duty of care that persists beyond the ending, the prohibition on using the relationship to secure compliance and the resulting conflict with the behavioural tradition, the status of the guardian in a placement, the young person's right to refuse disclosure, the cultural and religious considerations in the caregiver's response, and the avoidance of re-traumatisation.

## 14. Review and Discussion Questions

**Review and Discussion Questions**

1. Explain Bowlby's methodological objection to psychoanalysis and the ethological response.
2. State the four functions of the attachment system.
3. State the three conditions of attachment and explain why their separability matters clinically.
4. Explain the relationship between the attachment, the exploratory, and the caregiving systems.
5. Define the internal working model and state its three components.
6. Describe the developmental trajectory of the working model.
7. Explain the secondary revision of the working model and the clinical error of reading the adolescent's relationship difficulties as a regression.
8. Describe the strange situation and state the three child attachment categories with their behavioural signatures.
9. Explain why the disorganized category is described as a fright without solution.
10. State the four adult attachment categories and explain why they are not the adult versions of the child categories.
11. Describe the attachment matrix and read its four quadrants.
12. State the five principles of attachment-based therapy.
13. Describe the ABC, CFTSI, DDP, and MBT approaches and their evidence bases.
14. State the five core practices of attachment-based work.
15. Explain the significance of repair and of the prohibition on requiring reassurance.
16. State the four reasons the attachment perspective fits the adolescent period.
17. Describe the four adolescent attachment presentations and their interventions.
18. State the five components of the work with the caregiver.
19. State the four requirements of the relationship with the practitioner.
20. Describe the case of Nadia and state the two lessons it teaches.
21. Summarise the status of the evidence for the attachment research and for the interventions.
22. State the five limitations of the evidence base.
23. State the five strengths and the five limitations of the attachment perspective.
24. Explain the central cross-cultural finding about the strange situation and the methodological correction it produced.
25. State the seven ethical considerations for attachment-based work.

## 15. Practice Activities

**Practice and Application**

### Activity 34.1 — The Attachment Matrix (75 minutes, small group)

In groups of three, observe — or reconstruct from a placement — a family session involving a young person and their caregiver. Code the young person's behaviour in the session on the secure, preoccupied, dismissing, and disorganised axes, and code the caregiver's on the secure, preoccupied, dismissing, and unresolved axes. Read the resulting quadrant and write the intervention that follows from it. Then write the specific observation that would make you revise the reading. The exercise teaches both the instrument and the humility that the instrument requires.

### Activity 34.2 — The Bid Diary (five days, individual)

For five days, record every small bid you can observe in one relationship — a family member's, a friend's, a colleague's — and what the response was. Record the bid, the response, and whether the response was prompt and congruent. Then, with a second person, swap diaries and read theirs, and identify the bids that you would have missed. The exercise builds the observation skill that the whole attachment-based practice depends on, and the second stage, reading another person's record, is where the learning of what a bid looks like actually happens.

### Activity 34.3 — The Repair Rehearsal (60 minutes, pairs)

One student plays a sixteen-year-old who has just been told something painful by the practitioner, and the other plays the practitioner who has mis-handled it. The young person withdraws. The practitioner's task is to repair: to name what happened, to take responsibility, and not to require the young person to reassure them. Then reverse roles. Then write down the three things the practitioner said, and assess each against the requirement that the repair not be a request for reassurance. Most practitioners, including the students, make the repair into a request for reassurance in the first attempt, and the exercise is designed to make that visible.

### Activity 34.4 — The Cultural Audit of a Category (60 minutes, individual)

Take a case from placement and apply the attachment categories, and then audit each judgement against the cultural and material context of the family. For every classification, ask: what does this caregiver's behaviour mean in this family, in this community, in this household, given the pressures they are under? Then write the revised formulation, using the caregiver's own account of the situation. The most common finding is that at least one of the four categories was an artefact of the practitioner's expectation rather than a description of the child, and the exercise is the most direct preparation for the cultural work in Chapter 48.

## 16. Annotated Reading Pathways

**For the theory.** Read Bowlby (1969) for the foundational statement and Bowlby (1988) for the clinical papers, which is the most useful single book for a practitioner. Then read Ainsworth and colleagues (1978) for the strange situation.

**For the developmental argument.** Read Cassidy and Shaver's handbook for the comprehensive state of the field, and Crittenden (2009) for the most usable developmental summary.

**For the clinical work.** Read the DDP manual for the PACE stance and the "follow your lead" technique, and read the CFTSI manual. Then read the video-feedback literature, which is the technique most applicable to practitioners who do not work with infants.

**For the evidence and the critique.** Read the longitudinal attachment studies, the DDP and MBT trials, and the critical reviews of the attachment measures. The critical reviews are essential: the field's own handling

of its instruments' limitations is a model of professional self-criticism.

**For the cultural question.** Read the cross-cultural attachment literature, especially the work on the strange situation's context dependence and on caregiving in non-Western settings, and read the literature on attachment in families experiencing poverty and migration. The cross-cultural material is not a supplement to the theory; it is part of the theory.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Attachment Theory and Attachment-Based Therapy** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is bowlby, Ainsworth, and the translation of attachment research into treatment. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is family patterns, attachment, boundaries, communication, stories, and relational resources. The mechanism to keep in view is how interaction sequences and shared meanings distribute distress, protection, responsibility, and possibility across a system. The characteristic professional risk is blaming families, exposing a young person in unsafe joint sessions, or ignoring material conditions and individual needs. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in family meetings, school consultations, care networks, and individual sessions informed by systems thinking, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the

next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Tobias is fifteen and is seen in an integrated school and health team for difficulty trusting adults after several service changes. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Tobias's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Tobias explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on family patterns, attachment, boundaries, communication, stories, and relational resources. The first intervention is deliberately modest. Tobias chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Tobias has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions,

Tobias can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?

- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Attachment Theory and Attachment-Based Therapy

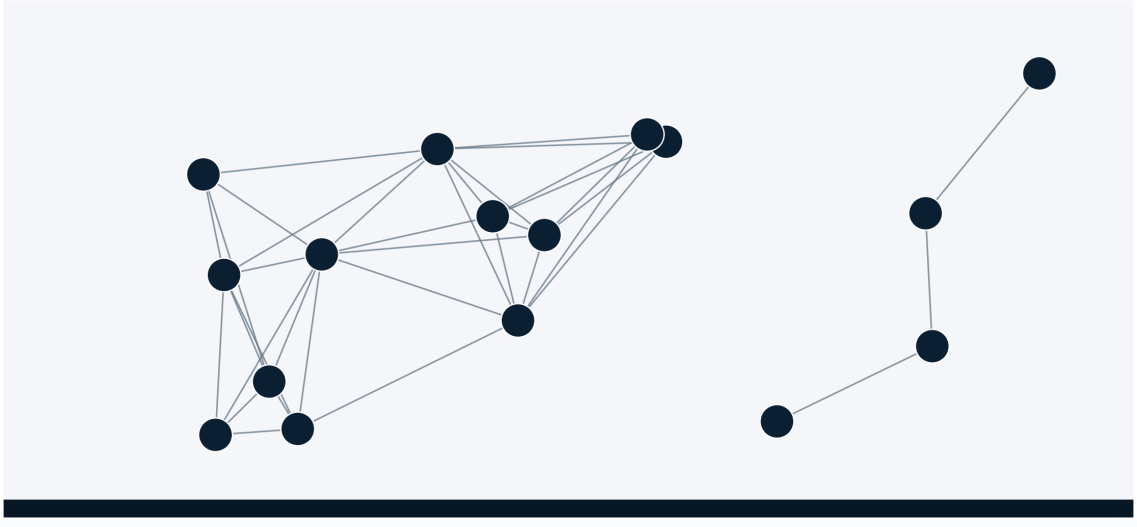
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Attachment Theory and Attachment-Based Therapy** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Attachment Theory and Attachment-Based Therapy** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Attachment Theory and Attachment-Based Therapy**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Attachment Theory and Attachment-Based Therapy to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 35

# Solution-Focused Brief Therapy and Strength-Based Practice

Scaling, exception questions, and the deliberate use of what is already working.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the development of the solution-focused school and the clinical problems that produced it.
- State the core assumptions of solution-focused practice and explain the clinical argument for each.
- Describe the five core skills: the miracle question, exception questions, the past question, the coping question, and the goal.
- Describe the scaling questions and explain their clinical use.
- Explain the concepts of the solution and the exception and their relationship to the problem.
- Apply the solution-focused approach to a case involving an adolescent and a family.
- Critically evaluate the cultural and ethical dimensions of solution-focused work, including the questions of language, of hope, and of the treatment of the problem.

## Chapter Overview

The solution-focused school began with a clinical observation that sounds trivial and is not. In the late 1970s, the family therapists in Milwaukee asked a family what had changed since their first appointment, and the answer was frequently: *nothing much*. The question was so ordinary that it reorganised the field, because it exposed the fact that the therapists had been working exclusively on the problem and had never asked what was working.

The approach that grew out of that question is a short-term, future-oriented, and deliberately non-exploratory therapy. Its core discipline is the **exception** — the times when the problem did not occur, or occurred less, or was less intense — and its argument is that the exceptions contain the solution, because the factors that are present in the exceptions and absent in the problem are the factors that produce the change.

The approach has become one of the most widely used in the world, and it is worth understanding why. The reasons are partly clinical and partly economic. It is short, which matters in services with waiting lists. It is compatible with a wide range of theories, so it can be used as a common language in a team. It does not require the client to have insight, which matters with young people. And it produces a specific, concrete, and time-limited goal, which is exactly what a family in crisis needs.

The approach's limits are equally real and worth stating at the outset. Its emphasis on the future can be experienced by some young people as a refusal to engage with a present that is intolerable, and the field's own term for this — **the tyranny of the positive** — was coined by a critic of the approach. Its language is relentlessly positive, and there are contexts in which positivity is a form of denial. And the evidence base, while good, is concentrated in specific populations and specific contexts.

This chapter presents the theory, the skills, the applications with young people, the evidence, and the critical analysis.

# 1. Historical Context

## 1.1 The Milwaukee brief therapy project

The brief therapy project at the University of Wisconsin–Milwaukee in the late 1970s was a research programme into the common factors in psychotherapy, and it was led by Steve de Shazer, whose background was in behaviour change and in communication theory.

Two features of the project were decisive. First, it was **empirical in a way that family therapy had not been**: the therapists systematically recorded the sessions, and they recorded the specific verbal and nonverbal behaviours of the therapists, and they analysed what the therapists actually did that distinguished the sessions in which clients improved. Second, the analysis found that the therapists' **questioning** accounted for a substantial proportion of the variance in outcome, and that the questions that predicted improvement were questions about the future, about the exceptions, and about the client's own resources.

The finding was not that the therapeutic relationship did not matter; the project's later work found that the relationship was a precondition. The finding was that, once the relationship was established, the specific behaviours of the therapist predicted the outcome, and that those behaviours were largely a matter of the questions asked.

### 1.2 The solution-focused brief therapy

The clinical practice that followed developed the model's techniques into the five core skills, and the practice was taught in a distinctive way: through a formal **training in listening**, in which the trainee learns to identify the client's own solution language as it appears in the conversation and to build the session around it. The training is unusually demanding and it is unusually effective.

The school's influence has been enormous and is best seen in the fact that solution-focused language is now used in services that have no connection to the school: in motivational interviewing, in coaching, in school counselling, in the management of chronic conditions, in the work with homelessness, and in the school-based prevention programmes of the 2000s.

### 1.3 The wider strength-based movement

Solution-focused practice is part of a larger movement that includes the strengths perspective in social work, the resilience literature in developmental science, the positive psychology that emerged in the 1990s, and the practice-based evidence movement. The shared proposition is that the questions asked of a client, a family, or a community determine the kind of information that the system produces, and that a system that is asked only about problems will produce only problems.

The proposition is not merely rhetorical. It has a technical consequence that a student should be able to state: **the questions a practitioner asks determine what the practitioner can see.** A practitioner who asks only about the problem will see the problem, and will become an expert on the problem, and will find that the problem is resistant, and will conclude that the client is resistant.

## 2. The Core Assumptions

### 2.1 The assumptions

The solution-focused approach rests on a small number of assumptions, and each of them has a clinical consequence.

**Every client has resources and strengths.** The assumption is not that the client is well or that the problem is not real; it is that the resources for the change exist somewhere, and the clinical task is to find them.

**Clients are the experts on their own lives.** The practitioner does not interpret, does not diagnose, and does not tell the client what is happening. The practitioner asks questions that help the client notice what they are already doing that works.

**Change has already happened.** This is the assumption that most distinguishes the approach and the one that most needs explanation. The client's life contains times when the problem was better, smaller, absent, or different, and these times are the raw material of the work. The exceptions are not a distraction from the problem; they are the solution in embryo.

**The future is the focus of the work.** The emphasis is on the next small step rather than on the last big one.

**The small can be a catalyst.** A small step that is achievable and that the client can verify produces a momentum that is disproportionate to its size, and the reason is that the small step is also evidence.

**Cooperation is the key.** The practitioner and the client work together on the problem, and the practitioner brings the question and the client brings the answer.

**The problem is separate from the person.** The person is not the problem, and this is the reframe that the approach offers to every client.

### 2.2 The solution and the exception

The **solution** is the behaviour, or the state of affairs, that the client wants more of. It is defined by the client, in the client's own words, and it may be entirely outside the problem: a young person who is being bullied may want to be "not frightened in the corridor", and that is the solution, and it is not the same as "not being bullied", and the distinction matters because the second may not be within the client's control.

The **exception** is a time when the problem did not occur, or occurred less severely, or was managed differently, and the exception is the search for the causal factors. The practitioner asks: what was different? What did you do? Who was there? What was happening in the other part of your life? The answers identify the factors that are present in the exception and absent in the problem.

**The exception is not the same as the solution.** The solution is what the client wants more of. The exception is a time when the client got some of it. The distinction is clinically important because the exception is evidence and the solution is the target, and a client who is asked to find the solution before the exceptions have been explored will often offer an aspiration rather than a description.

## 3. The Five Core Skills

### 3.1 The miracle question

**"Suppose that for some reason the problem got solved. What would be different?"** and then, if the client needs it, **"and what would you be doing?"** and **"and what would other people notice?"**

The miracle question is the signature technique of the approach, and its logic is worth understanding. It is a question about the future, it is deliberately large, and it is deliberately counterfactual. The counterfactual does the work: asking a young person to imagine the problem solved produces a description of the consequences of the solution, and the description is of a world in which the problem is not there, which is

information the client has and the practitioner does not.

**The therapist's discipline.** The therapist must resist the strong pull to ask the question in a way that suggests the answer, to ask a "realistic" version, or to move on to the next question. The miracle question works because it is asked as a genuine open question and because the client is allowed to answer it with something entirely impractical, and the impractical answer is often the most informative.

**With young people.** The miracle question is often better asked in the future tense and in the concrete: "If the thing with school got sorted out, what would your Tuesday look like?" The concrete form produces more usable detail.

## 3.2 Exception questions

Exception questions ask the client to describe a time when the problem did not happen, or happened less, or was handled better.

**"Was there a recent time when this was not a problem?"** and then, when the client has found one, **"What was different then?"** and **"What did you do that was different?"** and **"Who else was involved?"** and **"What was going on in the rest of your life at that time?"**

The exception questions have two functions. They **locate the solution** — because the factors present in the exception are the factors that make the difference. And they **disrupt the problem's hold** — because the problem's apparent all-encompassing quality is itself a distortion, and the exception is the data that corrects it.

**The therapist's discipline with exceptions.** The therapist must find a *recent* exception, and must resist the client's tendency to produce a very old one or one that is so distant that it is not usable. And the therapist must treat the exception as informative rather than as a lucky accident, because the treatment of the exception as an accident teaches the client that exceptions are rare and the search is hopeless.

**The exception and the small step.** The exceptions also identify the small steps, and the small steps are what the client does between sessions.

## 3.3 The past question

**"Was there a time when this was better than it is now? Or a time when it was even worse?"**

The past question serves a specific purpose: it locates the trend. A client who can identify that the problem has been improving slowly, however slightly, has a very different relationship with it from a client who experiences it as static or worsening, and the first client can be asked what has been helping.

The past question is also the technique for the young person who presents with a sense of hopelessness, because the question does not presume improvement: it asks about a time when it was *worse*, and the direction of travel is then established from the client's own material.

## 3.4 The coping question

**"What have you been doing to cope with this?"** and **"What is it that keeps you going?"** and **"How have you managed to keep going?"**

The coping question is the approach's answer to the question of resources, and it has a specific and important target: the coping that the client has developed is a *skill*, and the skill is usually already partly

generalised, and the therapist's task is to make it explicit and to extend it.

**With a young person who is in crisis, the coping question is often the first productive question in the entire session**, because it honours what they have done, and because the answer is usually more concrete than the description of the problem.

## 3.5 The goal

The **goal** is the specific, achievable, and time-limited target that the client sets, and the setting of a goal is the last and most important of the core skills.

**A well-formed goal** is: specific, so that the client will know when it has been achieved; achievable, so that the client believes it; and bounded in time, so that it can be checked.

The boundedness in time is the element most often missed, and it is what makes the goal a tool rather than a wish. "By the end of next week, I will have texted my cousin twice" is a well-formed goal. "I will be better" is not.

**The therapist's discipline.** The therapist does not set the goal, and does not improve it, and does not suggest a goal when the client is silent. A goal that the therapist has proposed and the client has accepted is not a solution-focused goal.

## 3.6 Scaling questions

The **scaling** technique asks the client to rate a dimension on a scale, and it is the most flexible of the school's techniques.

**"On a scale of zero to ten, where zero is the worst it has ever been and ten is the best you can imagine, where are you now?"** and then, **"And what would one point higher on the scale look like?"** and **"And what would one point lower look like?"**

The three questions are the whole technique, and each does something different. The **current rating** locates the client. The **"one point higher"** question identifies the immediate next step, and it is remarkable how much more specific a one-point shift is than the miracle question, because the one-point shift is within the client's own frame of reference for the scale and is therefore grounded in their own experience of the dimension. The **"one point lower"** question identifies what the client fears, and it is the question that surfaces the risk, and it is the question that the therapist should ask when the client is becoming complacent.

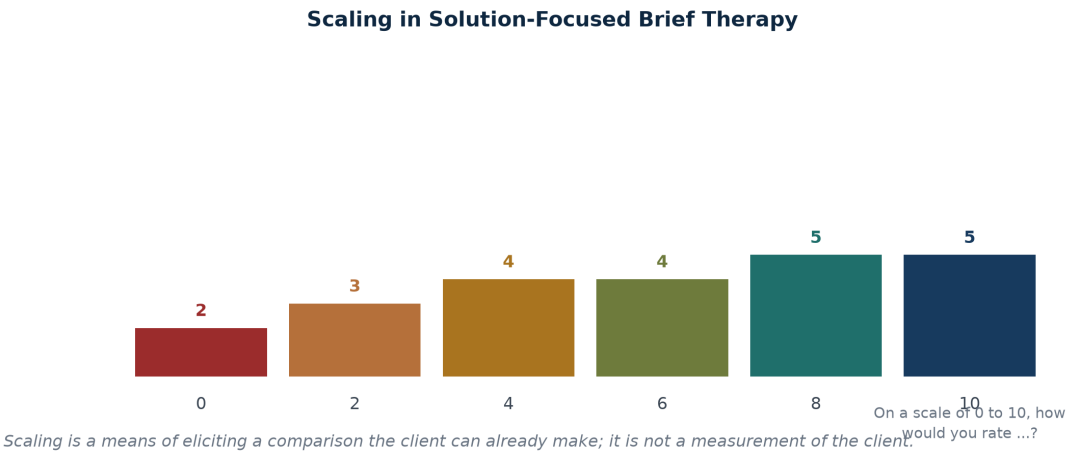


**Figure 35.25** The scaling question sequence, showing the current rating, the one point higher, and the one point lower, with the function of each in the session.

**Scaling in the session.** The scaling technique is also used on the *session* itself: "On a scale of zero to ten, how useful was that last ten minutes for you?" The practice of scaling the session and scaling the goal is one of the most distinctive and most immediately usable elements of the approach, and it is a good way for a student to begin practising the model.

## 3.7 Solution talk and problem talk

The most reliable single indicator of whether a conversation is solution-focused is the language it uses, and the distinction is worth learning as a listening skill.

**Problem talk** describes the problem in the third person, in the general, in the past, and in the abstract: *the thing with school*, *my son and his behaviour*, *I am always fighting with her*, *things have been really bad lately*. It is generalised, it excludes the client, and it contains no specific moment and no verifiable detail.

**Solution talk** describes a specific moment, in the present or the recent past, with the client in the first person, and with a detail that can be verified: *on Tuesday I got up at eight and caught the bus*, *last week I told my tutor I was coming back and then I left*, *I ate lunch in the canteen on Thursday and Finn was there*.

The practitioner's task in the conversation is to shift the talk from the first to the second, and the shift is accomplished not by telling the client to be more specific but by modelling the question that invites it. "Tell me about the problem with school" produces problem talk. "Tell me about the last time you went to school and it was okay" produces solution talk. "What did you do this morning?" produces solution talk.

Two practical notes follow. First, the shift is often achieved with a single word — the past tense for a future question, the first person for a third person. Second, and more importantly, the shift is a *social* process rather than a technical one: the client will begin to use solution talk when they experience that the practitioner is interested in the times things went better, and this is experienced as a change in what the practitioner wants, not as a change in the client's own thinking.

## 3.8 The practice in other settings

The solution-focused approach has been adopted more widely outside the therapy room than any other model in this book, and a student preparing for practice should know how it transfers.

**In schools.** The approach is used in school counselling with a striking consistency, and the reason is that it is quick, that it produces a written goal that the young person can take to the classroom, and that it does not require the young person to disclose. A school-based solution-focused session with a young person who is refusing to attend can be complete in fifteen minutes and can yield a goal that the form tutor can act on.

**In motivational interviewing.** The two approaches share a great deal: the focus on the client's own language, the focus on discrepancies between the stated values and the current behaviour, the resistance to telling the client what to do, and the eliciting of the client's own reasons for change. The scaling question and the "one point lower" question are structurally similar to the confidence ruler in motivational interviewing, and a practitioner who knows both will find the combination very powerful.

**In health and chronic illness.** The approach has been applied to diabetes management, to chronic pain, to medication adherence, and to weight management, and the clinical logic is the same: the exception search identifies what makes the behaviour possible, and the goal is a behaviour.

**In the justice system.** Solution-focused brief therapy has a substantial evidence base in community justice settings, and the reason is both clinical and practical: the clients are often hostile to the institution, they are often mandated, and the approach asks them no more than it needs to ask and produces a concrete action.

**In homelessness services.** The approach has produced some of the most encouraging results in the brief intervention literature, in a population that is typically difficult to engage and typically dropped out.

**With families in poverty.** The strengths-based practice literature, which grew out of the solution-focused work, has made a distinctive and important contribution: it has shown that the conventional deficit-based assessment systematically misdescribes families who are poor, because the conventional instruments ask about problems and the families have plenty, and the strengths-based instruments ask what is working and the families also have plenty, and the difference in the resulting assessment is a different family.

# 5. Solution-Focused Work with Children and Adolescents

## 5.1 The fit

The solution-focused approach is used more widely with young people than with any other population, and the reasons are worth understanding.

**It does not require insight.** A young person who cannot or will not articulate their difficulties can still answer the miracle question, the exception question, and the coping question, and the approach is therefore unusually accessible to a young person who is defensive, or inarticulate, or frightened, or who has been told by adults that their problem is bigger than they can manage.

**It is short.** A young person who has waited six weeks for an appointment and who suspects that the appointment will be another demand will engage with a short, concrete, future-oriented session in a way they will not engage with an open-ended exploration.

**It does not require the young person to be the problem.** The problem is separated from the person, and the young person is invited to be the expert on their own life, and this is a considerable relief to a young person who has been the identified patient in every previous attempt.

**It is compatible with the behavioural and the systemic work.** The exception question is, in the terms of Chapter 23, a question about the contingencies that were in operation; the small step is a graded task; the goal is a specification of a target behaviour with a time limit. The approaches fit together well.

**It produces something the young person can take away.** A written goal, a small step, a scale, and a telephone number are all things a young person can use between sessions, and a young person who is in trouble needs something to hold.

## 5.2 The specific modifications

**Use the child's language.** The approach's core discipline of using the client's own words is more important with young people than with adults, because the young person's words are also the material the young person will use outside the session. If a young person says the school is "a prison", the goal should be in the language of prisons, or at least should use the young person's words for the desired state.

**Ask the miracle question in the concrete.** "If the thing with school got sorted out, what would your Tuesday look like?" produces more usable detail than the abstract form, and it is easier for a young person to answer.

**Scale the small things.** The scale works particularly well with young people, and the "one point higher" question is the workhorse: "Where are you on a scale of zero to ten for how much you want to go to school?

What would one point higher look like?"

**Find the exception in the ordinary.** The exceptions with young people are frequently in the ordinary week: the good lesson, the day the tutor was away, the time the argument did not happen, the evening that was fine. The therapist's job is to get the granularity right.

**Use the coping question to establish the baseline of competence.** "How have you managed to keep going?" is often the first question that produces a competent description of the young person, and it changes the frame of the session.

**Set the goal with the young person and make it a behaviour.** A goal of "feeling better" cannot be checked. A goal of "texting my mum on Monday and Wednesday" can.

**Use the family.** The approach's techniques work with the whole family and they work particularly well with parents, because the coping question to a parent — "how have you managed to keep this together?" — is often the first time the parent has been asked anything other than what is wrong.

## 5.3 Solution-focused work with a family in crisis

A family in crisis is a good fit for the approach and a poor fit if it is applied naively. The specific cautions are as follows.

**Do not go too fast.** The "one small step" rule is right for a family in a stable situation and wrong for a family in which a young person is at risk. A family in crisis needs enough time in the session to be held, and the short session is a decision to be made deliberately rather than by default.

**Do not scale the safety.** Scaling the young person's suicidality, or the family's functioning, in the first session of a crisis is a misuse of the technique. The scale is for a dimension that the client can hold, and a scale on a crisis dimension produces a number that is meaningless and is experienced as a reduction of the crisis to a number.

**Use the exception to find what was there before the crisis.** The "what was different" question is the most useful question in a crisis, because the answer identifies what was working and has stopped working, and the work is often the restoration of something that has been lost rather than the creation of something new.

**The goal in a crisis should be a safety goal, and it should be co-constructed with the referrer.** The goal of not going to school is not a useful goal in a crisis; the goal of going to the school nurse's office at eleven, with an adult waiting, is.

## 5.4 The problem of the positive

The approach's language is relentlessly positive, and this is its most significant clinical liability. The phrase **the tyranny of the positive** was coined to describe the experience of a client who is invited to focus on their strengths at the moment when they most need to describe their pain, and who experiences the invitation as a demand that they perform wellness.

Three safeguards are available.

**Ask about the pain explicitly and in the same tone.** "I want to hear about the hard stuff too, and about the times when it is worse" is a legitimate and necessary question, and it is the safeguard.

**Do not imply that a difficulty is the client's responsibility.** The approach's language of "the problem is separate from the person" must be used carefully, because a young person who has been told that the

problem is theirs has had the framing imposed on them.

**Watch for the young person who is polite.** A young person who has learned to give the answer the adult wants will produce miracle answers and coping answers that are not true, and the practitioner's diagnostic task is to notice the discrepancy between the answer and the young person's presentation.

### 5.5 The problem of hope

The approach assumes that a future is available to be worked on, and the assumption fails in a number of circumstances that are common in the adolescent population.

**A young person who has no reason to want a future** — a young person who is suicidal, or who is in a family in which the future is genuinely uncertain — will produce answers to the miracle question that are either empty or despairing, and the practitioner must not treat the despairing answer as a failed miracle question.

**A young person for whom the goal has been confiscated.** A young person in a care placement whose every decision is made for them cannot set a goal, and the practitioner should work with what they can control, and should be honest with the system about the constraint.

**A young person whose future is genuinely not available** — where there is no realistic prospect of a stable home, or of safety, or of health — needs work that is not solution-focused, and the approach's optimism will be experienced as indifference if it is not matched by an honest assessment of the circumstances.

## 6. Case Illustration: The Young Woman Who Had Two Good Tuesdays

**Presentation.** Amira is seventeen and is referred by her school for "low mood and withdrawal". The referral describes a young woman who has stopped attending her college, who has stopped answering messages, who is "always in her room", and who has been "like this since October".

**The first session.** The practitioner does not begin with the problem. The practitioner begins with the coping question: "Before we talk about how things have been, I want to know how you've been managing. You've been through a lot this year — what's kept you going?"

Amira is quiet for a moment and then says, quite steadily: "Music. And my gran. And Tuesday." The practitioner asks what is special about Tuesday and Amira says that on Tuesdays she has a music lesson in town, and that she goes with a friend, and that she comes back and the evening is fine. The practitioner asks what happens on a Tuesday that does not happen on a Wednesday and Amira says: "Nothing happens. I just don't want to."

The practitioner asks a scaling question: "On a scale of zero to ten, where's your Thursday this week, and where's your Tuesday?" Amira says Thursday is a two and Tuesday is a seven. The practitioner asks what a three on Thursday would look like, and Amira says: "Getting out of bed before my dad shouts. And eating something that isn't in my room." The practitioner asks what a three would look like on the actual Thursday, and Amira says: "Get to college. Even for one lesson. And tell the tutor I'm coming."

**The exceptions.** The practitioner spends most of the session on the exceptions, and the exceptions are specific. On the Tuesday, Amira gets up at eight because she wants to catch the bus. On the Tuesday, she has something to wear that she has chosen. On the Tuesday, her phone is charged because she needs it for

her friend. On the Tuesday, her dad is working late, and her gran is there. The practitioner asks what else is different, and Amira says, after a pause: "I don't have to talk to anyone. In the tutor's office, I'm in a corridor and I don't have to speak."

**The formulation.** The formulation is not a depression formulation. The formulation is: Amira's week is structured by two things — a music lesson and the presence of her grandmother — and everything else is structureless, and the structureless days are the difficult ones. The withdrawal from the college is not a mood; it is the absence of the structure and the presence of the requirement to speak to people she does not know. Her mother, who is in the referral as a problem, is not in the formulation at all, and the practitioner notes that she has not yet heard from the mother, and she arranges to.

**The intervention.** Four elements.

*Element one: the goal.* Amira's goal, which she states herself, is: "By Friday, I go to the tutor's office and say I'm coming back, and I don't have to stay." The goal is specific, it is achievable, it is bounded in time, and it is a behaviour. The practitioner asks what she will do in the office and Amira says: "Stand at the door and say it. Then leave."

*Element two: the small steps.* The steps are derived from the exception, and they are the Tuesday factors applied to the difficult days. The first step is that Amira will get up and dress before her dad shouts, and the second is that she will charge her phone, and the third is that she will have something to wear that she has chosen. The purpose of the steps is stated explicitly: "You get dressed and charge your phone on a Tuesday because those are the things that make a Tuesday a Tuesday, and I'm asking you to try them on a Thursday, and if it works even a bit, that is evidence that a Thursday can be more like a Tuesday."

*Element one, revised: the grandmother.* The practitioner asks whether the grandmother could be involved and Amira says no, and the reason is that the grandmother is the person who looks after her and the family would be worried. The practitioner accepts this and does not pursue it, and the acceptance is itself an intervention, because it is the first time in the session that an adult has not pushed past a "no".

*Element three: the mother.* The practitioner sees the mother separately in the following week, and the mother's account is that Amira is "in her room all day, she's rude, she doesn't want to talk to me, she snapped at me on Sunday and I cried in the bathroom." The practitioner asks the mother the coping question — "How have you been managing?" — and the mother says, after a pause: "I don't know. I've just been going to work." The practitioner asks the mother to identify the last time she and Amira had a conversation that was not about a problem, and the mother cannot think of one. The practitioner asks the mother what Amira was like before October, and the mother says: "She was funny. She was really funny." And then she says: "I've been bringing her food up to the room. I thought that was helping."

The practitioner names the mechanism carefully: "I don't think you're doing anything wrong. But the food is the only contact you're having with her, and it's happening at her door, which means she doesn't have to come to you. And it's probably the only time you two talk. And if that's the only contact, then everything you want to talk to her about is going to go through that door, and she's going to close it."

The specific change: the food goes to the kitchen, and the mother and the daughter eat together once a week, on a fixed day, and the mother is asked to make one thing that is not on the ordinary rotation, and the conversation is not about the problem.

*Element four: the follow-up.* The session is booked for the following week, and the practitioner asks Amira to rate the session on the scale, and Amira says: "Seven." The practitioner asks what a seven-and-a-half would look like, and Amira says: "Texting my cousin. She keeps texting and I keep not replying and it's

starting to be weird." The practitioner takes this as the small step for the week, and it is the correct one, because it is the smallest social behaviour in the account.

**The outcome.** At six weeks, Amira is attending one lesson a week, has returned to the music lesson, and has replied to her cousin. Her mother reports that they eat together once a week and that "it's not brilliant but it's something". The college has not reported a full-time return, and the practitioner says clearly that this is not the outcome the referral wanted and is nevertheless the outcome that is durable.

**The interpretation.** The case illustrates the approach in full, and it also demonstrates its characteristic mechanism: the exception was located with precision, and the intervention was the transfer of the factors present in the exception to the days on which the problem occurred. The mother's daily delivery of food to the door was the sequence in the family system, and it was interrupted by the same logic, and the intervention with the mother was a single concrete change. And the therapist's discipline about the client's own words was what produced the formulation: the whole account was built on "Tuesday" and on what Tuesday contained, and no diagnostic formulation of a depressive disorder would have generated that intervention.

# 7. Evidence and Research Support

## 7.1 The status of the evidence

The solution-focused approach has a good evidence base, and it is stronger than its clinical reputation in some quarters would suggest.

**The brief therapy outcome literature is good.** The studies of brief therapy in general, in which the solution-focused approach is the most fully operationalised, show substantial effects on a range of outcomes and good retention.

**The research on the specific question types is the distinctive contribution.** The studies that recorded the therapists' questions and correlated them with outcomes found significant effects for the future-oriented and the exception questions, and the effects held after the therapeutic alliance was controlled for.

**The meta-analyses of the solution-focused approach report moderate-to-large effects** on depression, on the broad measures of psychological distress, and on the goal-attainment measures, and the effects are comparable with those of longer treatments in several populations.

**The evidence with adolescents is reasonable and growing**, and the approach is used extensively in school settings, and the school-based studies report good effects on the young people's measured outcomes and on the measures of school engagement.

**The evidence in specific high-risk populations is good.** The approach has been successfully applied in homelessness services, in the justice system, in chronic pain services, and in services for families with a young person at risk of removal from home, and the results in the homelessness literature in particular are among the most encouraging for a very brief intervention.

## 7.2 Limitations of the evidence

**The studies are small and heterogeneous**, and the model has been applied with considerable variation, and the fidelity measures are rarely reported.

**The measures are largely symptom and goal-attainment measures**, and the long-term outcomes are less well documented.

**The samples skew towards the mild and the voluntary**, and the young people in crisis are under-represented.

**The "positive outcome" findings are vulnerable to the response set of the participants.** A client who wishes to please a friendly practitioner who has asked them to describe a miracle will produce a miracle.

**The comparison with longer treatments is often unfair in either direction.** The studies frequently compare a brief solution-focused intervention with a longer treatment of a different theory, which confounds the brevity with the model.

# 8. Strengths and Limitations of the Solution-Focused Approach

## 8.1 Strengths

**It is accessible.** It requires no insight, no theory, and no trust in the therapist's expertise, and it works with young people who are resistant, inarticulate, or frightened.

**It is short and it retains people.** The approach has among the best retention rates in the psychotherapy literature, because people who are not helped do not come back.

**It is portable.** The five skills can be taught in an afternoon and used in any setting, and they are now used in services with no connection to the school.

**It is compatible with other modalities.** The exception question is a functional analysis in everyday language; the goal is a specification of a target behaviour; the small step is a graded task.

**It changes what the practitioner sees.** The question discipline changes the information the system produces, and a practitioner who has learned it becomes substantially better at seeing what is working.

**It is compatible with a working alliance.** The approach's posture of curiosity and respect is compatible with the person-centred conditions of Chapter 10, and the two are frequently combined.

## 8.2 Limitations

**It can trivialise.** The tyranny of the positive is a real and predictable harm, and a young person in pain can experience the approach as a demand that they perform recovery.

**It is not appropriate for every problem.** Where the problem is a danger, a symptom of a medical condition, or a consequence of a systemic failure, the focus on exceptions and goals is beside the point.

**It has no theory of aetiology, and this is a strength and a weakness.** It is a strength because it does not require a diagnostic formulation, and a weakness because the practitioner has no framework for understanding what they are seeing and no way of deciding what to do when the exceptions do not reveal a usable pattern.

**It can produce a compliant but unconfronted young person.** A young person who sets a modest goal, achieves it, and is congratulated has been given a success that is real and that may not change the underlying situation.

**The evidence does not address the severe cases**, and a service that adopts the approach wholesale will struggle with the young people it most needs to serve.

# 9. Cultural and Ethical Considerations

## 9.1 Culture and the language of the approach

The solution-focused approach's most powerful technique — using the client's own words — is also its most culturally sensitive, because the words are the culture.

**The miracle question assumes a future in which the problem is absent, and the future is culturally structured.** In a context in which the young person's future is materially uncertain, the question may be experienced as an accusation, and the answer may be despairing rather than evasive.

**"Strengths" are culturally specified.** The approach's assumption that the client's own language and the client's own people are the source of the strength is sound; the assumption that what the client values is what the client should work towards is not available, because the client's values are partly the values of a community that the practitioner may not understand, and in some contexts the young person's own stated goal will be a goal the practitioner regards as harmful.

**The exception search can be culturally loaded.** A young person in a family in which openness about the difficulty is itself dangerous may produce exceptions that are false, and the practitioner must be alert to the possibility that the exception is a performance.

**The language of the approach is individualistic**, and the "the problem is separate from the person" formulation is a claim about the person and the problem that does not transfer to every cultural frame, and in some settings the person and the problem are not separable in the way the formulation assumes.

## 9.2 Ethical considerations

**The obligation to acknowledge the pain.** A practitioner using this approach has an obligation to ask about the difficulty and to sit with the answer, and the approach's own literature now contains this caution.

**The obligation not to substitute positivity for safety.** A goal-setting process must not displace a safeguarding or a risk assessment.

**Informed consent to the approach itself.** A client should know what the approach does, and that it is brief, and that the practitioner is not going to explore the past in depth, and this should be said at the beginning rather than discovered at the end.

**The avoidance of coercion through goal-setting.** A goal that the client sets under the pressure of a therapist who is warm and encouraging and who has made the session pleasant is not a free choice, and the practitioner should notice the difference between a goal the client wanted and a goal the client produced to please.

**The equity issue.** The approach is culturally and economically attractive precisely because it is efficient, and a service under pressure may adopt it because it is cheap, and the risk is that it is then applied to the families who complain least. The approach works best with the families who can engage, and the families who cannot are the ones the service is under pressure to serve.

**The termination question.** A brief approach terminates quickly, and a young person who has experienced a short, warm, effective piece of work and then a termination may learn that relationships are brief, and the termination should be handled with the same care as any other.

## 10. Key Terms

**Key Terms at a Glance**

- **Solution-focused brief therapy** — A short-term, future-oriented, and non-exploratory therapy developed from the study of brief therapy in Milwaukee, in which the client's exceptions and resources are the primary clinical material.
- **The tyranny of the positive** — The experience of a client who is invited to focus on their strengths at the moment when they need to describe their pain, and who experiences the invitation as a demand to perform wellness.
- **Miracle question** — "Suppose that for some reason the problem got solved, what would be different?" The signature technique of the approach, in which the counterfactual produces a description of the consequences of the solution.
- **Exception question** — A question asking the client to describe a time when the problem did not occur, occurred less, or was handled better, and what was different about it.
- **Past question** — A question asking about a time when the problem was better or worse, used to locate the trend and to establish hope.
- **Coping question** — A question asking what the client has been doing to manage the problem, which identifies a skill that is already present and partly generalised.
- **The goal** — A specific, achievable, and time-bounded target set by the client, and the last of the core skills.
- **Scaling question** — A question asking the client to rate a dimension on a scale, followed by the "one point higher" and "one point lower" questions.
- **The one-point-higher question** — The question that identifies the immediate next step, grounded in the client's own frame of reference for the dimension.
- **The one-point-lower question** — The question that surfaces the client's fear and the risk, and the question to ask when a client becomes complacent.
- **Session scaling** — The practice of rating the usefulness of the session itself on a scale, and the most direct way for a beginner to learn the model.
- **Solution** — The behaviour or state of affairs that the client wants more of, defined by the client in the client's own words.
- **Exception** — A time when the problem did not occur, occurred less, or was managed differently, and the search for the factors present in it.
- **The distinction between the solution and the exception** — The solution is the target and the exception is the evidence, and a client asked for the solution before the exceptions have been explored will usually offer an aspiration.

**Key Terms at a Glance (continued)**

- **Solution language** — The client's own words for the desired state, which the practitioner uses verbatim and which is the primary material of the work.
- **The change has already happened** — The assumption that the client's life contains times when the problem was better, smaller, absent, or different, and that these times are the raw material of the work.
- **The small can be a catalyst** — The principle that an achievable and verifiable small step produces a momentum disproportionate to its size.
- **Problem is separate from the person** — The reframe the approach offers to every client, and one that must be used with care.
- **The questions determine the data** — The principle that the questions a practitioner asks determine what the system produces, and that a system asked only about problems will produce only problems.
- **The behavioural common factors** — The therapeutic alliance, the social contract, the expectancy of improvement, the client tasks, and the therapeutic feedback, and the approach's compatibility with the common factors model.
- **Cooperation** — The orientation in which the practitioner brings the question and the client brings the answer, in place of an expertise in which the practitioner brings the answer.
- **The small step** — The specific, doable action that the client takes between sessions, derived from the exception.
- **Question discipline** — The consistent use of the model's core questions, and the skill that separates a solution-focused practitioner from a generalist who asks the odd future-oriented question.
- **The training in listening** — The formal training in identifying the client's own solution language as it appears in the conversation.
- **Retain the client** — The principle that a client who is not helped will not return, and the approach's unusually good retention figures.

## 11. Chapter Summary

The solution-focused school began with the observation that therapists were working only on the problem and had never asked what was working, and it developed into one of the most widely used approaches in the world. The chapter traced the Milwaukee brief therapy project, in which the therapists' own recorded behaviour was analysed and the future-oriented and exception questions were found to predict outcome, and it placed the school within the wider strength-based movement and its shared technical proposition that the questions asked determine the information the system produces.

The core assumptions were stated with their clinical consequences, and the distinction between the solution and the exception was drawn: the solution is the target, the exception is the evidence, and a client asked for the solution before the exceptions have been explored will offer an aspiration.

The five core skills were described in detail, with the therapist's discipline for each: the miracle question, in which the counterfactual produces the description of the consequences of the solution and the practitioner must resist the urge to make the question realistic; the exception questions, which locate the solution and disrupt the problem's hold and must be recent and must be treated as informative rather than accidental; the past question, which locates the trend; the coping question, which identifies the skill; and the goal, with its three requirements of specificity, achievability, and boundedness in time, and the requirement that the client sets it. The scaling technique was described with the three questions that constitute it and with the one-point-higher and one-point-lower functions, and session scaling was identified as the most direct way for a beginner to learn the model.

The developmental and clinical fit with young people was developed through the five reasons the approach is widely used with this population, the six specific modifications for young people, the cautions for work with a family in crisis, and the two serious liabilities: the tyranny of the positive and the assumption of an available future. The three safeguards against the first and the circumstances in which the second fails were given.

The case of Amira demonstrated the approach's characteristic mechanism. The exception was located with precision — Tuesday, and everything Tuesday contained — and the intervention was the transfer of the factors present in the exception to the days on which the problem occurred, and the mother's daily delivery of food to the door was identified as the family sequence and interrupted by the same logic, and the whole formulation had been built out of the client's own words and would not have been produced by a diagnostic formulation of depression.

The evidence was summarised with its limits, and the strengths and limitations were set out, with the two most important limitations identified: that the approach can trivialise, and that it has no theory of aetiology, which is both its strength and its weakness.

The cultural analysis addressed the cultural structure of the future assumed by the miracle question, the cultural specificity of strengths, the possibility that the exception search can be culturally loaded, and the individualistic framing of the approach. The ethical section addressed the obligation to acknowledge the pain, the obligation not to substitute positivity for safety, informed consent to the approach, the avoidance of coercion through goal-setting, the equity issue that a service under pressure may adopt an efficient approach and apply it to the families who complain least, and the termination question.

## 12. Review and Discussion Questions

**Review and Discussion Questions**

1. Explain the clinical observation that produced the solution-focused school.
2. Describe the Milwaukee brief therapy project and its central methodological contribution.
3. Explain the technical proposition that the questions determine the data.
4. State the seven core assumptions and the clinical consequence of each.
5. Distinguish the solution from the exception and explain why the distinction matters.
6. State the miracle question and explain the role of the counterfactual.
7. State the therapist's discipline with the miracle question.
8. State the exception questions and explain their two functions.
9. State the therapist's discipline with the exceptions, including the recency requirement.
10. Explain the purpose of the past question and its use with a hopeless young person.
11. State the coping question and explain its value with a young person in crisis.
12. State the three requirements of a well-formed goal and explain the boundedness in time.
13. Explain the therapist's discipline in the goal-setting conversation.
14. State the three scaling questions and the function of each.
15. Explain the use of session scaling and its value for a beginning practitioner.
16. State the five reasons the approach is widely used with young people.
17. State the six specific modifications for young people.
18. State the three cautions for work with a family in crisis.
19. Explain the tyranny of the positive and the three safeguards against it.
20. Explain the assumption of an available future and the three circumstances in which it fails.
21. Describe the case of Amira and state the mechanism it demonstrates.
22. Summarise the status of the evidence for the approach.
23. State the six strengths and the six limitations of the approach.
24. Explain the four cultural considerations for solution-focused work.
25. State the seven ethical requirements for this work.

## 13. Practice Activities

**Practice and Application**

### Activity 35.1 — The Five Questions (60 minutes, individual)

Write out and answer, in writing, all five of the core questions for a problem of your own, and then write the answers as a client might give them. Then write the miracle question as a therapist tends to ask it by mistake, and compare. The exercise is the fastest way to learn the model's discipline, and the comparison of the two forms of the miracle question makes the difference between the real and the implied question visible.

### Activity 35.2 — The Exception Search (90 minutes, field-based)

Take a young person from placement and find three exceptions — times when the difficulty was smaller, or absent, or handled better. For each, write the "what was different" analysis: the specific factors, the people, the time of day, the state of the other part of the life. Then write the small step for each. Most students find that the exceptions are ordinary and that the factors are mundane — a charged phone, a chosen outfit, a friend present, a door open — and the discovery that the treatment is the transfer of the mundane is the point.

### Activity 35.3 — Scaling the Session (three sessions, in pairs)

In pairs, run a fifteen-minute conversation in which the practitioner asks only the five core questions, and at the end scales the session and asks the "one point higher" question. Then reverse roles, with the second student now acting as the practitioner, who should ask fewer questions and listen more. The second round is the instructive one, because it demonstrates the difference between a practitioner who is asking questions and a practitioner who is listening for the answer.

### Activity 35.4 — Auditing a Miracle Question (60 minutes, small group)

In groups of three, take a real referral and write the miracle question as it would be asked in that case, in the exact words the client would use, followed by the scaling question and the exception question. Then have each group member read the set aloud and identify the question that is most likely to produce a useful answer, and the one that is most likely to produce a polite one. Then write the version of the miracle question that would work with a young person who has been in trouble with adults before. The final step is the practical lesson of the chapter.

## 14. Annotated Reading Pathways

**For the model.** Read de Shazer (1985) and then O'Connell (2003), which is the clearest clinical handbook and the most usable with young people.

**For the research.** Read the original Milwaukee project papers and the later research on the question types, and read Shonk and Greasley (2015) for the contemporary account. The question-type research is the most interesting evidence in the book, because it is the evidence for a specific technique rather than for a treatment package.

**For the practice.** Read O'Connor and McGee (2016), which is written for parents and educators and is exceptionally clear about the mechanics. Then practise the five questions, because the model is a skill and not a set of propositions.

**For the evidence.** Read the meta-analyses of solution-focused therapy and of brief therapy, and the school-based studies. Read the criticisms alongside them.

**For the critique.** Read the literature on the tyranny of the positive, and read the critical accounts of brief therapy in complex cases. The critique is important because the approach's virtues and its failures are the

same feature seen from two sides.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Solution-Focused Brief Therapy and Strength-Based Practice** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is scaling, exception questions, and the deliberate use of what is already working. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is family patterns, attachment, boundaries, communication, stories, and relational resources. The mechanism to keep in view is how interaction sequences and shared meanings distribute distress, protection, responsibility, and possibility across a system. The characteristic professional risk is blaming families, exposing a young person in unsafe joint sessions, or ignoring material conditions and individual needs. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 7. Apply the method | Use the chapter's core procedures in family meetings, school consultations, care networks, and individual sessions informed by systems thinking, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support,

timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Ines is fifteen and is seen in a school counselling service for low mood and withdrawal from friends. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Ines's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Ines explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on family patterns, attachment, boundaries, communication, stories, and relational resources. The first intervention is deliberately modest. Ines chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Ines has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Ines can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be

sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Solution-Focused Brief Therapy and Strength-Based Practice

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Solution-Focused Brief Therapy and Strength-Based Practice** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

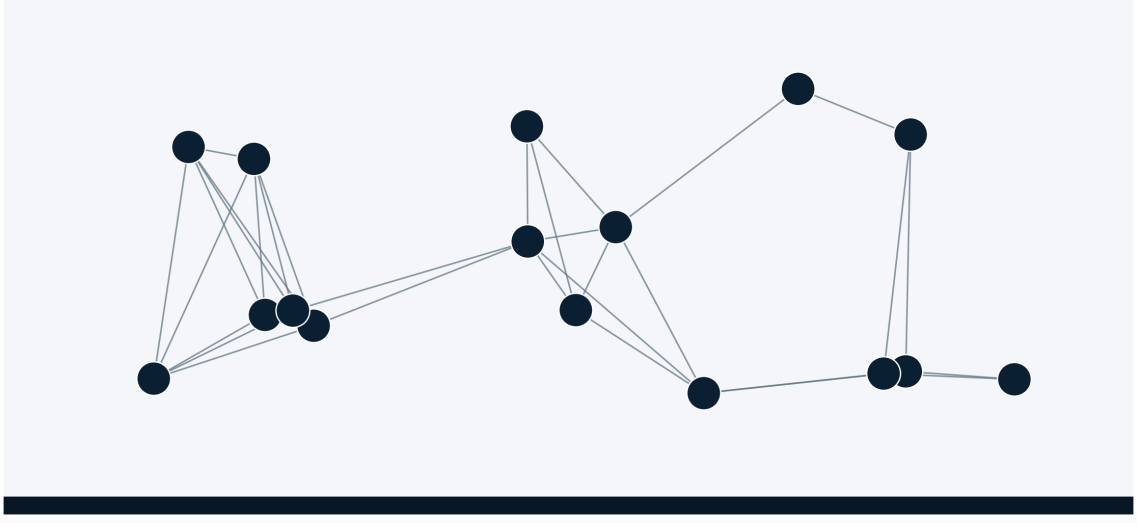
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Solution-Focused Brief Therapy and Strength-Based Practice** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Solution-Focused Brief Therapy and Strength-Based Practice**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a



discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Solution-Focused Brief Therapy and Strength-Based Practice to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 36

# Narrative Therapy and the Re-Authoring of Lives

Externalisation, unique outcomes, and the collaborative reconstruction of adolescent identity.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the development of the narrative therapy movement and describe the intellectual context in which it emerged.
- State the core concepts of narrative therapy, including the idea of the person as the author of their own life, the externalisation of the problem, and the re-authoring.
- Describe the techniques of externalisation, the naming of the problem, the mapping of its influence and its influence on the young person, the unique outcomes, and the re-authoring.
- Explain the use of documents, letters, and the therapeutic group in narrative practice.
- Apply the narrative framework to a case involving an adolescent and a family.
- Critically evaluate the cultural and ethical dimensions of narrative work, including the questions of whose story is told, of power, and of the relationship between the personal narrative and the material circumstances.

## Chapter Overview

Narrative therapy is the most recent of the family therapies in this book and the one with the most substantial intellectual debt to the wider human and social sciences. It came out of the late 1980s in Australia and New Zealand, and it was shaped by three sources that practitioners in the helping professions rarely combine: literary theory, particularly the structuralist and post-structuralist analysis of narrative; feminist epistemology, particularly the critique of the way in which knowledge about women has been produced by the professions; and the intellectual traditions of post-colonialism and of the social sciences' interest in how identities are constituted by discourse.

Its central claim is that **a person's identity is constituted by the stories they live by and tell about themselves, and that the stories are not the person**. This sounds abstract and is in fact highly practical. A young person who has lived for two years with the story "I am the one who ruins everything" has organised their behaviour around that story, their relationships around it, and their expectations about the future around it. The story is not a description of the person. The story is a framework through which the person has made sense of a life that has been genuinely hard, and the framework is now the thing that is producing the outcomes.

The practice of narrative therapy is therefore the practice of helping a young person to identify the stories that are organising their life, to examine them, to find the exceptions to them, to develop what the work calls **unique outcomes** — the moments and the events that do not fit the dominant story — and to use those unique outcomes to begin to author a different account of their life.

The approach is the most explicitly political of the therapies in this book, in the sense that it is concerned with how power operates in the production of knowledge, and this is both its greatest contribution and the source of its most substantial difficulties, which are addressed in Sections 9 and 10.

## 1. Historical Context

### 1.1 The development

The movement grew out of the family therapy practices of Michael White and David Epston in Melbourne and Auckland, from the mid-1980s. Both were family therapists with a social work and a literary background, and both were frustrated by two features of the family therapy of the period: its assumption that the family was a self-contained system that could be understood by mapping it, and its silence about the larger social structures within which families lived and about the power relations within them.

The break with the family therapy tradition was sharp. The structural and strategic schools treated the family as a system whose patterns could be mapped, and the narrative therapists asked a prior question: **by what criteria is this family understood to be a family at all?** A family that includes a violent father and an abused child is not a family in the way that the systemic models assume, and the framework of the family is itself a product of a moral and political judgement.

### 1.2 The intellectual sources

**The literary and post-structuralist analysis of narrative.** The structuralist narratologies of Propp, Todorov, and Genette, and the post-structuralist work of Barthes, Derrida, and Ricoeur, provided the analytic vocabulary: the distinction between the story and the discourse; the concept of the **fabula** as the raw material of lived events and the **syuzhet** as the organising shape given to them; the concept of the **narrative frame**, which selects certain events and excludes others; and the concept of the **absent or excised text**, the parts of the story that the frame excludes.

**Feminist epistemology.** The critique of the professional claim to know the truth about a client, particularly a woman, and the analysis of the ways in which a professional discourse can constitute the identity of the person it describes, came from the feminist critique of the therapies and the feminist research tradition.

**Post-colonial and social constructionist thought.** The analysis of how identities are constituted within discourses of culture, race, gender, and class, and the concept of the "othering" of people by the dominant discourse, informed the practice's treatment of the problem as an agent.

**Social work practice research.** The practice-based research movement in social work, of which the Australian and New Zealand family therapy tradition was a part, contributed the emphasis on the small, the local, and the specific.

### 1.3 The reception

Narrative therapy has been adopted in a very large number of settings, and it is used in services that have no connection to family therapy, in schools, in community mental health, in social services, in services for refugees, and in services for domestic violence. Its influence extends well beyond the practice of the model: the concept of the externalisation is used in coaching, in education, in organisational change, and in the self-help literature, and the **therapeutic conversation** in its modern form is discussed in Chapter 58 of this book.

## 2. The Core Concepts

### 2.1 The person as the author of their life

The foundational claim is that **a person is the author of their life**, and the word "author" is doing specific work. An author does not write a book in a single stroke; an author writes, revises, and re-writes, and a book

is the product of many drafts. The claim is therefore not that the young person has complete control over what happens to them, and the practice is careful to say so, but that the young person has a role in the shaping of the account of their own life, and that the account is a *draft* rather than a sentence.

Three corollaries follow.

**Identity is not fixed.** If the identity is constituted by the story, and the story is a draft, then the identity is revisable.

**The problem is not the person.** The problem is a thing that does things to the person, and it is the subject of a story, and it has interests of its own.

**Meaning is made, not found.** The meaning of an experience is not in the experience; it is in the account given of it, and the account can be different.

## 2.2 Externalisation

**Externalisation** is the practice of separating the person from the problem, so that the problem becomes an object that can be seen, described, named, and examined, and the person becomes the subject of their own life rather than the object of the problem's.

The classic example in the literature is the young person who says of their drinking, "The Drink took over my life." The externalisation takes the sentence and changes the grammar: "the drink" is given the attributes of an agent — it is powerful, it is persuasive, it takes over, it is cunning — and the young person is given the attributes of a subject who is acted upon and who can resist.

**The practice of externalisation** has a technical vocabulary, and the practitioner should be able to name it.

**Naming the problem or naming it differently.** The name is the young person's own, and the practitioner sometimes suggests a name and sometimes asks. "The Worry" and "The Fog" and "The Voice" are names that appear in the literature, and they are usually funny, and the humour is a feature: it is what makes the problem nameable without it being an insult.

**Writing the problem's influence.** "What does the worry do to you? What does it make you do?" and the answer is written down, often by the young person themselves, and often in the form of a list.

**Writing the problem's influence on the young person's influence on others.** "What does the worry make you do to your mum? What does it make you do to your friends?" The second question is the crucial one, because it locates the problem in the young person's life as an agent with power, and it makes the young person's own actions explicable.

**Identifying the unique outcomes.** "Are there any times when the worry doesn't have as much power? What did you do to make that happen?" and this is the heart of the practice.

**Authoring a new story.** "If the worry is not in charge, what would your life look like? How would your friends know? What would be different at school?" and the new account is written.

## 2.3 The problem's influence and the young person's influence

The **problem's influence** is the network of effects that the problem has on the young person's life: what it prevents, what it makes them do, what it costs them. The **young person's influence** is the network of effects that the young person has on their own life and on others: what they do that makes things better, what they are good at, what they influence in other people.

The practice of mapping both is the most structured technique in the model, and it is usually done on paper: a diagram with the problem at the centre, arrows going out to the effects it has, and arrows going in from the areas of the young person's life in which they have influence.

The clinical significance is that the second map is almost always thinner than the first, and this is the point. The young person has been living in a world in which the problem is the most powerful thing in it, and the discovery that they already have influence in some areas — however small — is the beginning of a different account.

## 2.4 Unique outcomes

A **unique outcome** is an event, a moment, a feeling, a thought, or a piece of learning in the young person's life that does not fit the dominant story, and that therefore opens a space for a different story.

The criteria are specific, and the practitioner should be able to state them.

**The unique outcome must be the young person's own.** It is not something the practitioner suggests and it is not something that happened to them.

**It must be a specific event, not a generalisation.** "I was able to tell my dad I was not going to the party" is a unique outcome. "I am a more assertive person" is not.

**It must be a departure from the dominant story.** If it fits the story, it is not a unique outcome, and a practitioner who cannot find one has usually asked the wrong question.

**It must be sufficiently detailed to be re-told.** The detail is what makes the re-authoring possible, because the re-authoring works by re-describing the same event with a different meaning.

**It must be linked to a skill or a preference or a value that the young person already has.** The unique outcome is not a fantasy; it is evidence of a capacity that already exists.

## 2.5 The dominant story and its problems

The **dominant story** — in the older literature, the "problem-saturated story" — is the account of the self that the young person lives by, and the practice of naming it is a distinctive and important step.

A dominant story is characterised by: a **subject position**, which is the self that the story requires the young person to occupy, usually a self that is the cause of the problem; a **plot**, which is the sequence that the story tells; and a **moral**, which is the conclusion the story draws about the young person and about the world.

The dominant story of a young person referred for behavioural problems in school frequently runs something like: "I am the one who causes trouble, and trouble follows me everywhere, and there is nothing to be done about it." The story is coherent, it is widely reinforced by the responses of others, and it is self-fulfilling: a young person who is the one who causes trouble behaves in the way that confirms the story, and the confirmation is read as evidence for the story.

**Naming the story** is done carefully and with permission. The practitioner asks: "How would you describe someone in your situation? What would you say is the story about you?" and the young person's own words are used, and the question "What is the effect of this story on your life?" opens the examination.

## 2.6 The re-authoring

The **re-authoring** is the process of rewriting the account of the young person's life so that it includes the unique outcomes, and it is the outcome of the whole practice.

The re-authoring is not the same as the positive reframe of the solution-focused school, and the difference is worth stating. A positive reframe replaces a negative account with a positive one. A re-authoring expands the account, and the expansion makes room for the unique outcomes, and it does not require the negative account to have been false. The young person who has been bullied did not imagine it, and the re-authoring does not require them to say otherwise; it requires them to be able to say that the bullying did not determine the rest of their life, and to point to the specific evidence.

The technique of the re-authoring is to return to a specific unique outcome and to re-describe it, in detail, with the young person dictating, in their own words, and then to ask the questions that extend the account: "How does this change your understanding of what happened? If this is who you are in some situations, what does that mean for the other situations? Who else would have to change their story to make room for this?"

The last question is the one that makes the work systemic, and it is the question that distinguishes narrative therapy from a purely individual practice.

# 3. The Techniques in Detail

## 3.1 Externalising conversations

**The grammar of externalisation.** The work is done in the language. "The problem makes you do" becomes "You do" and "the problem" becomes the subject. "The Worry" is given a name, a personality, a set of characteristics, and an agenda. A young person who says "the worry takes over my body" is invited to describe what the worry does, and the describing is the intervention, because the young person is now observing the worry rather than being inside it.

**The questions that externalise.** "What does the problem do to you?" "What does the problem want?" "How does the problem talk to you?" "What would the problem say if it could speak for itself?" "What does the problem do to make sure you do what it wants?" These questions are the technique, and they are asked slowly, and they are asked in a tone of genuine curiosity.

**The rules of externalising questions.** They are asked of the problem and not of the person. They are asked more than once, because the first answer is usually a summary. They never suggest the answer. And they are not asked in a way that triviallyises: the question "what does the problem want?" presupposes that the problem wants something, and for a young person who has been told that their problem is their own fault, the presupposition is the intervention.

## 3.2 The documents

The **documents** are the most distinctive feature of the narrative practice, and they are of three kinds.

**The letter from the problem.** A letter written by the problem to the young person, in the problem's voice, describing what it has done to them and what it wants. It is usually written by the young person, sometimes dictated to the practitioner, and it is often the first document because it is the most engaging and the least threatening.

**The letter to the problem.** A letter written by the young person to the problem, often as a reply, in which the young person tells the problem what it may and may not do from now on. This is the beginning of the boundary-setting, and the letter is often more useful than a conversation because it is in the young person's own words and it can be re-read.

**The letter to the young person.** A letter from the practitioner to the young person, written at the end of a piece of work and given to them, and the letter is a record of what the practitioner has noticed and what the practitioner values, and it is often the artefact that the young person keeps.

**The "take-away" letter.** The most common of the documents: a letter written by the young person to themselves, to be read at a difficult moment, containing the unique outcomes and the re-authored account. Its efficacy depends entirely on the young person's own words.

**The value of the documents.** They externalise the conversation from the session; they slow it down, because writing is slower than speaking; they give the young person something to hold; and they make the re-authoring concrete, because the re-authored account has to be written in sentences.

### 3.3 The therapeutic group

The **therapeutic group** — also called the storytelling group — is the group in which the re-authoring is done collectively, and it is a distinctive and powerful element of the practice.

The structure is: each member tells their story to the group in a structured way; the group listens for the unique outcomes; and the group members then ask questions, and the questions are restricted to two forms — "what was different?" and "how come?" — with the rule that no advice, no interpretation, and no "have you tried" is permitted.

The rules are the therapeutic mechanism, and they are the point of the whole technique. The questions "what was different?" and "how come?" are questions that the young person answers, and the answers are the unique outcomes, and the group is a machine for producing them.

**The evidence for the group format is good**, and the group is used with adolescents, with families, and with adults, and it is the format in which the approach is most clearly distinct from the individual work of the other therapies in this book.

### 3.4 The role of documents in the school setting

In a school, the documents have a specific and useful function: they can be shared with the teachers. A letter from the problem, written by the young person, that describes what the problem does in the classroom and what it wants, can be given to a form tutor, and it converts the teacher's response from a reaction to the young person into a response to the problem. This is a small intervention with a large effect, and it is one of the most practically useful applications of the model in a school setting.

# 5. Narrative Work with Children and Adolescents

## 5.1 The developmental fit

Narrative therapy is used extensively with young people, and the reasons are developmental as well as practical.

**Adolescence is the period of the identity narrative.** The central developmental task of the period is the construction of a coherent account of who the young person is and who they are becoming, and the accounts available in the surrounding discourse — from the family, from the school, from the peers, from the media — are in competition with the one the young person is building.

**The dominant story is often assigned from outside.** A young person who is in trouble, who is unwell, or who is in a family that is under strain is the recipient of a story that is spoken about them rather than by them, and the developmental risk is that they will adopt it.

**The adolescent's capacity for narrative is fully developed.** The ability to hold a complex account of one's own life, to see that there are different ways of telling the same events, and to recognise that the account is a construction rather than a fact, is a late adolescent capacity, and the practice is appropriate to it.

**The group's format is developmentally suited**, because adolescents are highly attentive to the questions asked by their peers and highly sensitive to the possibility of being told what to do.

## 5.2 The initial conversation

The narrative first session is distinctive, and a student should know what it involves.

**The practitioner tells the young person what the practice does.** The explanation is direct: "I am not going to ask you why you do the thing you do. I am going to ask you what the thing does to you, and what you do to it, and I am going to help you write down the parts of your life that the thing has not managed to reach. And at the end we are going to write a new version of your story that includes those parts." The young people who stay with the practice are frequently the ones who have never been told that the problem is not their fault.

**The practitioner asks the young person to describe the problem in their own words**, and does not supply a label. "What do the adults at school call it? What do you call it?" The name the young person chooses is usually more vivid and more externalising than the diagnostic one, and the use of the young person's own name is the beginning of the externalisation.

**The practitioner locates the problem's network.** "Where does this thing show up in your life? What does it do to your sleep? To your friends? To what you do at the weekend?" and the answers are written down, and the writing is the map of the problem's influence.

**The practitioner looks for the unique outcomes from the first session**, and the first session should end with at least one, however small, and the therapist should not leave the session without one, because the young person's experience of the session will be determined by whether the practice delivered what it promised.

## 5.3 Working with the school and the family

**With the school.** The letter from the problem is the most useful document in a school setting, and the practitioner should explain to the young person how it works before it is written, so that the young person can decide whether they want it shared. A letter from the young person that says "The Panic makes me do the breathing and it tells me everyone is watching and it makes me go to the toilet and it makes me get sent out of class" gives the teachers something to work with that is not the young person.

**With the family.** The narrative approach is unusually well suited to family work, because the practice of the family is to find the dominant stories that circulate in the family and to examine them, and the re-authoring is a collective act. The practitioner can map the family's dominant stories — "we're the family where nothing works", "she's the one who was always the difficult one", "we don't talk about that" — and the unique outcomes can be located in the family's own history.

**The systemic re-authoring question.** "Who else would have to change their story to make room for this?" is the question that connects the individual work to the family and to the school, and it is the question that a practitioner who is working systemically should always ask.

## 5.4 The work with the unique outcomes

The process of developing a unique outcome requires patience, and a student should know the common obstacles.

**The young person cannot find one.** This is common in the early sessions, and the usual reason is that the question is too big. The remedy is to reduce the time scale: not "a time when the anxiety didn't happen" but "a moment in the last week when you felt more like yourself", and the smaller the frame the more likely the

young person is to find something.

**The young person finds only negative unique outcomes.** A young person who says "the only time it was better was when I was on drugs" has found a genuine unique outcome, and the practitioner's task is to find the *components* of that experience. "What did you like about being on drugs? What did it give you that you wanted?" and the answer — the relief, the numbness, the confidence, the not-caring — is then located in other parts of the young person's life where the same thing can be had differently. This is the technique that the literature calls the **re-authoring of the unique outcome** and it is one of the most useful and least discussed.

**The young person produces a unique outcome that is too small.** "I was okay for about ten minutes" is a valid unique outcome and it is frequently dismissed by the practitioner, and it should not be, because the ten minutes can be examined for the factors present in it and the factors can be extended.

**The young person resists the re-authoring.** Some young people are invested in the dominant story, because it is a story in which they are the protagonist and it has a certain dignity, and the practitioner should note that the dominant story usually protects the young person from certain kinds of responsibility and from certain kinds of hope, and the examination should be gentle.

### 5.5 The limits with young people

**Not every young person can or will work this way.** The practice requires a capacity for reflection and a tolerance for ambiguity, and a young person in acute crisis, or with a very limited cognitive capacity, or with a very short attention span, may not be able to.

**The re-authoring can become a demand.** A young person who has been told that they must find their unique outcomes and who cannot, has been given another task they will fail, in a practice that promised them that they were the author.

**The problem is sometimes real and does not need externalising.** A young person who is being abused needs the abuse stopped, and the externalisation of "the abuse" into a separate agent, however therapeutically elegant, can be heard as a dilution of the reality.

## 6. Case Illustration: The Young Woman Who Had Become the Problem

**Presentation.** Keziah is sixteen and has been excluded from two schools in the past year. The referral is from her current school, which is worried about her attendance and about a fight in the corridor. Keziah's mother attends the first appointment and says, before the practitioner has said anything, "It's the same as it was with her father."

**The first individual session.** The practitioner does not begin with the history. The practitioner begins with the question: "What do the people at school call it? And what do you call it?" Keziah says: "They call me a behaviour problem. I call it the Black Hole." The practitioner asks what the Black Hole does, and Keziah says: "It eats everything. It ate my friends. It ate my year. It comes in at nine and it's there all day and it eats everything I try to do." The practitioner writes this down, and Keziah watches the words being written, and the practitioner says: "Can we keep going? What else does it eat?"

Keziah says: "It ate my music. It ate going to see my aunt. It ate my grades, but honestly the grades were gone before the Black Hole." The practitioner asks whether there is anything it has not eaten, and Keziah

thinks and says: "It hasn't eaten my swimming."

**The unique outcome.** The practitioner develops the swimming. "Tell me about the swimming." Keziah talks for twenty minutes without interruption. She swims four times a week, before school, at a pool her aunt drives her to, and the times are the best parts of her week. The practitioner asks what is different about the swimming, and the answers are precise: she is in the water and nobody can talk to her; she is doing a thing she is good at; she is with a coach who tells her what to do and does not have a mood about it; and her phone is in her bag.

**The mother's account.** In the joint session, the mother says that Keziah has always been "a handful" and that she was exactly like her father, and the practitioner asks the mother, gently, to say more about the father. The mother says that he was "a lovely man until he drank" and that he left when Keziah was three, and that she has spent thirteen years being careful that Keziah does not become him. The practitioner does not pursue this, but the practitioner does ask one question: "What did Keziah look like at three?" and the mother says: "She was the funniest child. Absolutely." And she stops, because she has heard it.

**The dominant story.** The practitioner names it explicitly in the session with Keziah: "So the story is that you are going to end up like your dad, and everything you touch turns into the Black Hole, and there is nothing you can do about it. And you have been living inside that story since you were three." Keziah says: "That's my mum's story. That's not mine." The practitioner asks: "So what is your story?" and Keziah says: "My story is that I am the person who is in trouble." And then she says, after a pause: "And that other people decide what that means."

**The re-authoring.** The re-authoring is done with a document. The practitioner asks Keziah to write a letter to the Black Hole, and suggests the first line: "I know what you want." Keziah writes, and the letter is three paragraphs long, and the third paragraph is: "You are not allowed in the pool. You are not allowed at my aunt's. If you want to be fed, feed me at breakfast, not at nine o'clock at night." The practitioner reads it and asks: "Are you sure this is what you want to send?" and Keziah says: "Yes."

**The systemic work.** The letter is shared with the mother, with the form tutor, and with the swimming coach. The form tutor's response is the most striking thing in the case: the teacher, who had been receiving the letter as an account of a difficult pupil, writes back a note saying that the Black Hole "sounds exhausting" and that the pupil is "not the problem, then". The mother writes back to Keziah a note that is in the third person — she says that she has realised she has been writing Keziah's story for her — and it is the first time the two have spoken in six months.

**The outcome.** At three months Keziah is in one school, is attending four days a week, is still swimming four times a week, and is in contact with her mother. The fight in the corridor has not recurred. The school has not made any formal change to her plan, which the practitioner regards as a missed opportunity, and the practitioner has a further four sessions and uses them to work with the mother and with the school on the question of the expectations.

**The interpretation.** The case illustrates the model's distinctive operations. The problem was named by the young person, and the naming was an externalisation; the unique outcome was located with precision and its components were identified; the dominant story was named, and the naming revealed that it was a story written *about* Keziah rather than by her, and the young person's own correction — "and that other people decide what that means" — was the pivot of the case. The re-authoring was done in the young person's own written words, and the document was the mechanism of the change. And the systemic question — who else has to change their story — was answered productively, because the teacher and the mother each had a story

about Keziah that they had never examined, and the letter from the problem gave them the material.

# 7. Evidence and Research Support

## 7.1 The status of the evidence

The evidence for narrative therapy is good in a specific and unusual way, and a student should be able to describe it accurately.

**The outcome research is the strongest in the family therapy field.** The studies that have used standardised outcome measures, and the practice-based research that has used single-case designs, have produced consistent findings of substantial improvement, and the effect sizes reported in the reviews are among the largest in the family therapy literature.

**The research on the distinctive outcomes is the most interesting contribution.** The studies of the *distinctive outcomes* — the specific changes in the young person's own language and in their own account that the research identifies as the markers of a successful narrative therapy — have identified a remarkably consistent set: the young person begins to use the problem's name less and their own attributes more; the unique outcomes become more detailed and more numerous; the young person begins to attribute change to their own actions; and the language of the dominant story shifts.

**The research on the group format is good**, and the studies of the storytelling group have found substantial effects and good retention.

**The evidence with young people is substantial**, across schools, community mental health, and family settings.

**The evidence base has been criticised on methodological grounds**, and the criticisms are worth knowing: the trials are frequently small, the fidelity of the delivery is difficult to measure and is rarely reported, and the practitioners who conduct them are often the developers of the model.

## 7.2 Limitations of the evidence

**The measures of the practice's distinctive mechanism are retrospective and interpretive**, and the identification of a "distinctive outcome" depends substantially on the researcher's judgement.

**The trials are few and small**, and the confidence intervals are wide.

**The generalisability to other cultures and other languages is uncertain**, given the practice's roots in a specific intellectual context.

**The evidence does not address the complex presentations**, and the practice with young people with severe mental health needs, with neurodevelopmental conditions, or with acute risk is largely untested.

# 8. Strengths and Limitations of Narrative Therapy

## 8.1 Strengths

**It is a theory of identity that is developmentally apt.** The account of the young person as an author of their own account is a better fit for the adolescent than most of the theories in this book.

**It locates the problem outside the person**, and it does so in a way that a young person can feel.

**It produces artefacts.** The letters and the documents are tangible, they belong to the young person, and they often outlast the therapy.

**It is compatible with systemic and family work**, and the re-authoring of a family story is a natural extension of the individual practice.

**The group format is efficient and powerful**, and it is unusual in producing a real sense of a collective practice.

**It gives the practitioner something to do when nothing is working.** The externalising questions work in almost any circumstance, and they work when the young person will not talk about the problem.

**It is explicitly attentive to power**, and it has produced some of the clearest ethical writing in the therapy field.

### 8.2 Limitations

**It can be used to individualise a structural problem.** This is the most serious criticism and it is discussed at length in Section 10.

**It requires a capacity for reflection that some young people do not have**, and the practice has relatively little to offer the young person in acute crisis.

**It is difficult to learn well.** The externalising questions are easy to learn and easy to misuse, and the practice's discipline lies in the quality of the listening, which is not teachable by a manual.

**Its conceptual foundations can be opaque in practice**, and the philosophical apparatus can obscure what the practitioner is actually doing.

**The measures of the practice are weak**, and the field has invested more in the articulation of its theory than in the evaluation of its outcomes.

## 9. Cultural and Ethical Considerations

### 9.1 The politics and the practice

Narrative therapy is the most explicitly political of the approaches in this book, and the practitioner should be able to state both the value of that and the danger of it.

**The value.** The practice's attention to how the dominant discourse constitutes identities is a genuine contribution, and it is what allows a young person who has been labelled to be understood as a person rather than as a label. The observation that a young person's difficulties are frequently produced by the responses of others to them — the school's avoidance, the family's worry, the referral — is clinically important, and the practice gives the practitioner a way of working with it.

**The danger.** The practice's language of the "dominant story" can be turned into an account in which the young person's difficulties are the product of other people's narratives, and in which the young person is thus not responsible for anything. A young person who has been sexually assaulted, or who has developed a serious mental illness, is not a person whose account has been imposed. The practice's own literature has been critical of this tendency in recent years, and the correction is that the story is not the reality, and the events are not the story.

## 9.2 Culture, identity, and the dominant story

**The dominant story is often a cultural story.** A young person who is a member of an ethnic minority in a majority population, who is an immigrant, who is a young person in a family with a particular religious practice, may be living inside a dominant cultural story about people like them, and the practice's externalising questions may be the most direct way of working with that.

**The practice's origins are in a particular intellectual tradition**, and a practitioner who uses the externalising questions should know something about the structuralist and post-structuralist theory and about the feminist critique of the professional claim to know, because the questions make claims and the claims should be able to be defended.

**Naming the problem in a particular way can be culturally loaded.** A name given to a problem in one tradition may carry a specific theological or moral meaning in another, and the practitioner should ask.

**The re-authoring can overwrite the family's or the community's account.** A young person who is invited to author a new account of their life may be implicitly invited to author a *Western individualist* account, and the young person who has a strongly communal sense of self may find the practice strange or offensive.

## 9.3 Ethical requirements

**The consent to externalise is not automatic.** A young person must consent to the practice, and the consent should be informed, and the young person should be told that the practitioner will be asking about the problem in a particular way.

**The confidentiality of the documents.** A letter from the problem contains material the young person may not want a parent or a teacher to read, and the practitioner must establish what may be shared before the document is written rather than after.

**The power of the practitioner over the young person's account.** The practitioner is the one with the questions, and the young person may come to believe that the practitioner has a view about the right account. The discipline is to be genuinely curious, and to notice the times when the practitioner's preferred direction is being imposed.

**Not every problem is a story.** A young person with a medical condition, with a neurodevelopmental condition, or with a substance dependence requires treatment, and the re-authoring is not a substitute for it.

**The practitioner's own position.** A narrative practitioner is not a neutral observer of a story, and the practitioner who is part of a dominant discourse is likely to reproduce it inadvertently, particularly in the questions they think to ask. This should be examined in supervision.

**The social conditions.** The practice's own framework insists that the problem is produced in a social field, and the practitioner who externalises a young person's difficulties while ignoring the conditions in which the young person lives has done the practice's work in name and its opposite in substance. A young person whose problem is a school that is unsafe, or a family that is exhausted by two shifts of work, or a housing situation that is impossible, needs those things changed, and a re-authored story is not a substitute.

# 10. Key Terms

## Key Terms at a Glance

- **Narrative therapy** — The practice developed by White and Epston in which the young person's identity is understood as constituted by the stories they live by, and in which the work is the re-authoring of those stories.
- **The person as the author of their life** — The foundational claim that the account of a life is a draft, revisable, and made by the person whose life it is.
- **Externalisation** — The practice of separating the person from the problem so that the problem becomes an object that can be seen and described, and the person becomes the subject of their own life.
- **The grammar of externalisation** — The shift from "the problem makes you do" to "you do", in which the problem is given the attributes of an agent and the person the attributes of a subject.
- **Naming the problem** — The practice of giving the problem a name, usually the young person's own, and of writing that name down.
- **The problem's influence** — The network of effects the problem has on the young person's life: what it prevents, what it makes them do, and what it costs them.
- **The young person's influence** — The network of effects the young person has on their own life and on others, and the map that is usually thinner than the first and always more useful.
- **Unique outcome** — An event, moment, feeling, thought, or piece of learning that does not fit the dominant story and that opens a space for a different one.
- **The five criteria of a unique outcome** — The young person's own, a specific event rather than a generalisation, a departure from the dominant story, sufficiently detailed to be re-told, and linked to a capacity the young person already has.
- **Dominant story** — The account of the self that the young person lives by, with its subject position, its plot, and its moral.
- **Problem-saturated story** — The older term for the dominant story, in which the young person is the cause of the problem.
- **Re-authoring** — The process of expanding the account of the young person's life so that it includes the unique outcomes, without requiring the negative account to have been false.
- **The difference between a reframe and a re-authoring** — A reframe replaces a negative account with a positive one; a re-authoring expands the account and makes room for the exceptions.
- **The letter from the problem** — A letter written in the problem's voice describing what it has done and what it wants, usually written by the young person.

## Key Terms at a Glance (continued)

- **The letter to the problem** — A letter written by the young person to the problem, in which the young person sets the limits on what it may do.
- **The letter to the young person** — A letter from the practitioner recording what they have noticed and what they value.
- **The take-away letter** — A letter the young person writes to themselves, containing the unique outcomes and the re-authored account.
- **The therapeutic group** — The group in which the re-authoring is done collectively, with the listening restricted to the questions "what was different?" and "how come?".
- **The two permitted questions** — "What was different?" and "How come?", and the exclusion of advice, interpretation, and suggestions.
- **The re-authoring of the unique outcome** — The technique of locating the components of a negative unique outcome and finding them in other areas of the young person's life.
- **The systemic re-authoring question** — "Who else would have to change their story to make room for this?", which connects the individual work to the family and the school.
- **The fabula and the syuzhet** — The raw material of lived events and the organising shape given to them, from narrative theory.
- **The narrative frame** — The structure that selects certain events and excludes others, and the reason that the events excluded from a young person's story are the clinical target.
- **The excised text** — The parts of the story that the frame excludes, and which the practice seeks to recover.
- **Post-structuralist narrative analysis** — The intellectual tradition that treats meaning as made in discourse rather than found in events.
- **Feminist epistemology** — The critique of the professional claim to know the truth about a client, particularly a woman.
- **The problem is not the person** — The reframe that narrative practice offers, and its two corollaries in the externalising work.
- **Meaning is made, not found** — The proposition that the meaning of an experience lies in the account given of it and that the account can be different.
- **The document in the school setting** — The letter from the problem used to convert the teacher's response from a reaction to the young person into a response to the problem.
- **The dominant cultural story** — The account available in a society about a category of person, which the practice's externalising questions can address directly.

**Key Terms at a Glance (continued)**

## 11. Chapter Summary

Narrative therapy emerged in the late 1980s from a combination of literary theory, feminist epistemology, post-colonial thought, and social work practice research, and its central claim is that a person's identity is constituted by the stories they live by and tell about themselves, and that the stories are not the person. The claim is practical rather than abstract: the story through which a young person has organised a genuinely difficult life is now producing the outcomes.

The intellectual sources were described and the development of the movement in Australia and New Zealand was traced, including the sharp break with the family therapy tradition and the prior question the practitioners asked: by what criteria is this family understood to be a family at all.

The core concepts were developed in full. The person as the author of their life was described with its three corollaries — that identity is not fixed, that the problem is not the person, and that meaning is made rather than found. The externalisation was described with its technical vocabulary: the naming of the problem, the writing of the problem's influence, the writing of the problem's influence on the young person's influence on others, the identification of the unique outcomes, and the authoring of a new story. The problem's influence and the young person's influence were described as the two maps, with the observation that the second is almost always thinner and that the discovery of the young person's existing influence is the beginning of a different account.

The unique outcome was described with its five criteria, and the dominant story with its subject position, plot, and moral. The re-authoring was described and distinguished from the positive reframe: a reframe replaces, a re-authoring expands, and the expansion does not require the negative account to have been false.

The techniques were described in detail: the externalising questions and the rules for them; the four documents and their specific uses, in the therapy room, in the school, and in the letter to the young person; and the therapeutic group with its two permitted questions, which are the mechanism of the practice.

The developmental fit with young people was developed through the identity narrative, the externally assigned dominant story, the adolescent's capacity for narrative, and the group's suitability. The initial conversation was described, and the specific modifications for the school and the family were set out, including the systemic re-authoring question. The four obstacles to developing a unique outcome were described with their remedies, including the re-authoring of a negative unique outcome, which is one of the most useful and least discussed techniques in the model.

The case of Keziah demonstrated the model's distinctive operations. The problem was named by the young person and the naming was the externalisation; the unique outcome was located with precision and its components identified; the dominant story was named and the young person's own correction — that other people decide what that means — was the pivot; the re-authoring was done in her own written words; and the letter from the problem gave the teacher and the mother the material to examine the stories they had been telling about her.

The evidence was presented with its unusual structure: the outcome research is among the strongest in the family therapy field, the research on the distinctive outcomes is the most interesting contribution and has identified a consistent set of markers, and the criticism of the methodological quality is legitimate. The strengths and limitations were set out, and the principal limitation — the individualisation of a structural problem — was identified.

The cultural and ethical analysis was substantial. The politics of the practice was examined from both sides: its value in allowing a young person who has been labelled to be understood as a person, and the danger of an account in which the young person is not responsible for anything. The cultural questions were addressed: the dominant story is often a cultural story, the practice's intellectual origins carry commitments that should be known, the naming of a problem can be culturally loaded, and the re-authoring can overwrite a communal account of the self. The ethical requirements closed the chapter: the consent to externalise, the confidentiality of the documents, the power of the practitioner over the young person's account, the recognition that not every problem is a story, the practitioner's own position, and the social conditions, which the practice's own framework insists upon and which a re-authored story cannot substitute for.

## 12. Review and Discussion Questions

**Review and Discussion Questions**

1. Explain the three intellectual sources of the narrative therapy movement.
2. State the central claim of narrative therapy and explain why it is practical rather than abstract.
3. State the three corollaries of the person as the author of their life.
4. Describe the practice of externalisation, with its technical vocabulary.
5. Explain the significance of the problem's influence and the young person's influence maps.
6. State the five criteria of a unique outcome.
7. Define the dominant story and state its three components.
8. Explain the difference between a reframe and a re-authoring.
9. State the rules of the externalising questions.
10. Describe the four documents and their uses.
11. Explain the therapeutic group and state the two permitted questions.
12. State the four reasons the approach is used with young people.
13. Describe the initial conversation with a young person.
14. Explain the use of the letter from the problem in a school setting.
15. State the systemic re-authoring question.
16. Describe the four obstacles to developing a unique outcome and the remedy for each.
17. Explain the re-authoring of a negative unique outcome.
18. Describe the case of Keziah and state the four features of it that generalise.
19. Summarise the status of the evidence and the distinctive outcomes research.
20. State the six strengths and the six limitations of the approach.
21. Explain the political dimension of the practice from both sides.
22. State the four cultural considerations for narrative work.
23. State the seven ethical requirements for narrative practice.

## 13. Practice Activities

**Practice and Application**

### Activity 36.1 — The Externalising Question Set (60 minutes, individual)

Write a full set of externalising questions for a specific problem you have encountered, then rewrite each one so that it could only be answered by the problem and not by the person. Then write the variant of each question that would inadvertently re-internalise the problem, and mark it. The exercise teaches the grammar of the practice, and the second half of it teaches the discrimination that distinguishes a practitioner who has internalised the discipline from one who has only learned the questions.

### Activity 36.2 — Finding a Unique Outcome (90 minutes, field-based)

Take a young person from placement and find one unique outcome: a specific event, in the last month, that does not fit the dominant story. Write it out in the young person's words, in the detail in which they described it. Then identify the components — who was present, what was happening, what the young person was doing, what they were wearing, where they were, what the mood of the setting was. Then write the small step that transfers one component into a context where the problem usually operates. The exercise is the core technique of the chapter, and the component analysis is the part that practitioners most often skip and that makes the difference between an outcome and a wish.

### Activity 36.3 — The Therapeutic Group (90 minutes, small group)

In a group of four or five, one member tells a short story of a difficulty, and the others are restricted to the two permitted questions — "what was different?" and "how come?" — for five minutes. Then the storyteller reports what they noticed. The group then processes what it was like to be restricted in this way, and what it was like to receive only those questions. Most groups find the restriction surprisingly hard and the questions surprisingly powerful, and both findings are the point.

### Activity 36.4 — The Dominant Story Audit (75 minutes, individual)

Take a young person from placement and write their dominant story in three sentences, in the third person, as it would be told by the school, by the family, and by the young person. Then write the "who else would have to change their story to make room for this?" answer for each. Then write the practical step for the two people whose stories are most clearly shaping the young person's outcomes. The audit is the exercise that connects the narrative work to the systemic and consultative work of Chapters 33 and 56, and it is the most useful single exercise in the chapter.

## 14. Annotated Reading Pathways

**For the theory.** Read White and Epston (1990) and then White (2007), and read Bruner (1990) for the account of narrative as a mode of human reality. Ricoeur (1984) is the philosophical source and is worth reading in the first part only.

**For the practice.** Read White and Stone (2008) and Epston and White (1995). Then read the group format literature, which is the most immediately usable part of the practice.

**For the intellectual sources.** Read the feminist epistemology literature on the professional claim to know, and read the post-colonial and social constructionist literature on discourse and identity. A student who knows these sources will use the externalising questions with more care and with far less mystification.

**For the evidence.** Read the outcome studies and the distinctive outcomes research, and read the critical appraisals alongside them.

**For the critique.** Read the critiques of narrative practice for its treatment of structural problems and for its individualistic framing, and read the feminist and post-colonial critiques from within the field. The field's own self-criticism is the most useful preparation for working with it responsibly.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Narrative Therapy and the Re-Authoring of Lives** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is externalisation, unique outcomes, and the collaborative reconstruction of adolescent identity. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is family patterns, attachment, boundaries, communication, stories, and relational resources. The mechanism to keep in view is how interaction sequences and shared meanings distribute distress, protection, responsibility, and possibility across a system. The characteristic professional risk is blaming families, exposing a young person in unsafe joint sessions, or ignoring material conditions and individual needs. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 7. Apply the method | Use the chapter's core procedures in family meetings, school consultations, care networks, and individual sessions informed by systems thinking, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support,

timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Kofi is fifteen and is seen in a community adolescent clinic for grief following a major family change. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Kofi's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Kofi explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on family patterns, attachment, boundaries, communication, stories, and relational resources. The first intervention is deliberately modest. Kofi chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Kofi has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Kofi can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be

sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Narrative Therapy and the Re-Authoring of Lives

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Narrative Therapy and the Re-Authoring of Lives** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Narrative Therapy and the Re-Authoring of Lives** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Narrative Therapy and the Re-Authoring of Lives**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a

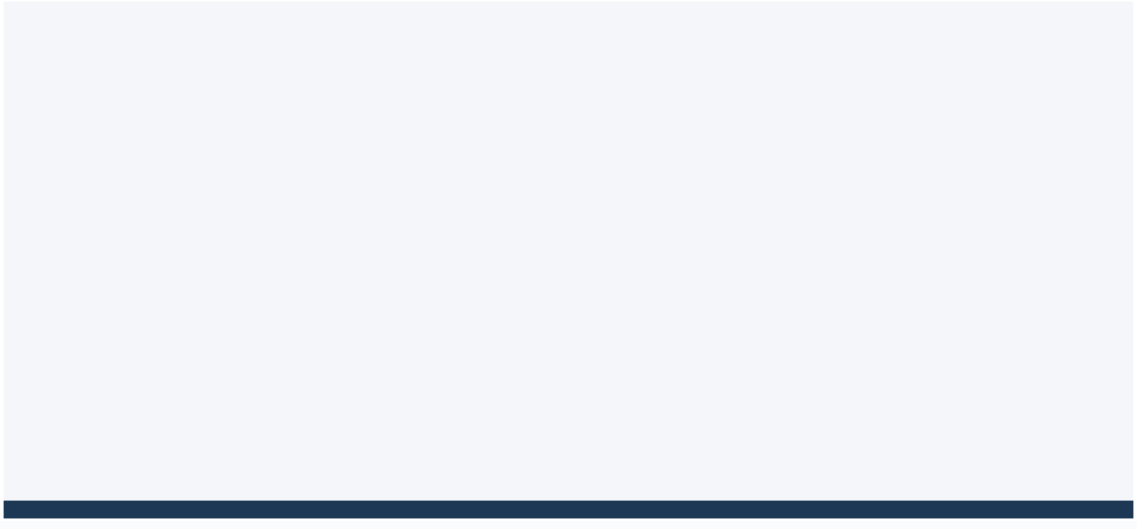
discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Narrative Therapy and the Re-Authoring of Lives to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

PART VI

# Emotional, Trauma-Informed, and Somatic Practice

Theories and methods that work with feeling, with the body, and with the developmental consequences of threat: emotion-focused work, trauma-informed phases, bilateral stimulation, and somatic regulation.



CHAPTERS IN THIS PART

43 Somatic, Sensorimotor, and Polyvagal-Informed Practice

CHAPTER 37

# Emotion-Focused Therapy

Greenberg's model of emotion regulation, the change point, and emotion-focused work with youth in distress.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the development of emotion-focused therapy and describe the clinical problems that produced it.
- State the principles of the emotion-focused model, including the position that emotion is the primary datum in therapy.
- Describe the model of emotion as a response to a need, and the categories of emotion the model identifies.
- Explain the concept of the change point and the two components of the process.
- Describe the emotional processing steps and the in-session emotion coaching.
- Apply the emotion-focused framework to a case involving an adolescent in emotional distress.
- Critically evaluate the cultural and ethical dimensions of emotion-focused work, including the questions of the cultural status of emotional expression and of the relationship between emotion and need.

## Chapter Overview

Emotion-focused therapy, in the form Leslie Greenberg and colleagues developed it, is unusual in this book in making the client's **emotional experience** rather than the client's thoughts, behaviour, or relationships the primary object of the work. Its founding observation was clinical and unremarkable: **clients change when they are able to identify, experience, and express their core emotions, and they do not change when they do the other things first.**

That observation was in part a reaction to a specific and widely felt failure of the cognitive therapies. Some clients arrive in cognitive therapy able to dispute their thoughts perfectly and leave unchanged, and the reason is that the problem is not in the thoughts. The client believes "I am worthless" and disputes it accurately — "I have got a job, I passed my exam, my aunt says I'm fine" — and the dispute changes nothing, because the feeling of worthlessness is not generated by the belief and is not removed by its refutation. The feeling is generated by an unmet need, and the needs are the clinical target.

The model has two further features that make it valuable with young people. The first is that it is **brief and focused**: the treatment has a limited number of sessions, a specific target emotion, and a specific procedure, and a young person who has been offered years of weekly sessions that produce no change is often well served by an approach that names a target and a timeframe. The second is that it is **developmentally consonant with the adolescent's task**: the adolescent's central developmental work involves the construction of a new self, and the emotions of that period — the shame, the anger, the grief, the anxiety — are the raw material of the work of becoming an adult, and the model treats them as such rather than as symptoms to be eliminated.

The chapter presents the model, the theory of emotion, the change point, the processing steps, the developmental adaptations, and the critical analysis, which includes the question of whether the model's account of emotion is culturally universal, and it is not.

## 1. Historical Context

### 1.1 The two foundations

The model has two intellectual sources, and both are in this book already.

**The client-centred tradition of Chapter 10.** The empathic attunement, the congruence, and the understanding of the client's frame of reference, and the finding that the conditions of the relationship are themselves therapeutic.

**The cognitive tradition of Chapter 16.** The technique of disputing maladaptive thoughts, which Greenberg did not abandon but repurposed: the cognitive disputation becomes one of several ways of responding to an emotion, and it is the *least* effective of them for most clients.

### 1.2 The development

Greenberg and colleagues began the work in the late 1970s at the University of British Columbia, initially as a research programme comparing a structured, emotion-focused treatment with a structured cognitive treatment for depression. The design was unusual in asking the researchers to code the process of therapy in detail, and the coding produced the finding that changed the field: **emotional change, rather than cognitive change, was the best predictor of improvement**, and the improvement in emotion in the session was the best single predictor of improvement in the session.

The programme then developed into a series of controlled studies that established the specific procedures, and the model was extended from depression to a wide range of presentations, including the anxiety disorders, the eating disorders, the interpersonal problems, the trauma-related presentations, and the problems of couples, and it was adapted for young people.

### 1.3 The place in the field

Emotion-focused therapy is not a mainstream school, and its position is unusual: it has a good research base, a well-specified protocol, and relatively limited clinical adoption. A student should be aware of the reasons, and they are instructive.

**The model requires a level of emotional processing that not every client can reach.** The model's procedures depend on a client who can access, identify, and stay with a core emotion. A young person with a very restricted emotional range, with a very high level of dissociation, or with a very limited capacity for reflection may not be able to do what the model asks, and the field's own position is that these presentations need a longer course of preparatory work.

**The model requires a trained practitioner.** The procedures look simple and are not, and a badly delivered emotion-focused session in which the practitioner pushes the client toward a feeling the client cannot bear is not a neutral event.

**The model's account of emotion is under-specified.** The theory of emotion as a response to a need is elegant and is not a theory of emotion in the sense that the affective science would recognise, and a student who wants a developmental account of the emotional system should read the affective science as well as Greenberg.

## 2. The Core Principles

### 2.1 Emotion as the primary datum

The model's foundational claim is that **emotion is the primary datum in therapy**, and that the other elements — cognition, behaviour, and the relationship — are in the service of emotion.

The claim is not that cognition is unimportant. It is that the cognitive intervention is subordinate: a belief is examined because it is generating or blocking an emotion, and a behaviour is examined because it is serving an emotional function, and the alliance is examined because a rupture in it will block the emotional work.

## 2.2 The nature of emotion in the model

Greenberg's account of emotion has four components, and a student should be able to state them.

**Emotion as a response.** Emotion is a response to a need — the need for a secure attachment, the need for autonomy, the need for control, the need for approval, the need for a sense of worth, the need for a connection with others, the need for a sense of identity. The primary emotions are organised in relation to these needs, and the specific emotion reflects the specific need and the specific way in which it is being frustrated.

**Emotion as adaptive.** Every emotion serves a purpose. Anger mobilises against a violation; shame mobilises against exposure; sadness mobilises against loss; fear mobilises against threat. The problematic emotions are not the ones that are wrong in themselves but the ones that are misdirected, excessive, or aimed at the wrong target.

**Emotion as tolerable and changeable.** Healthy emotions are felt, expressed, and then resolved. A primary emotion that is adequately processed ends; the problem arises when a secondary emotion — the feeling that arises in the reaction to the primary one — blocks it. Guilt is a secondary emotion that typically arises in the reaction to anger, and it blocks the anger and the anger's work.

**Emotion as transcending.** The most developed part of the model's account is the proposal that the highest form of emotional life is a form of transcendence in which the self is expanded beyond the narrowness of the immediate situation, and the "solution" emotions in the model — pride, confidence, calm, and a sense of the other as a potential ally — are understood as the forms of emotional transcendence.

## 2.3 The categories of emotion

The model's categories of emotion are clinically useful and a student should be able to use them.

**Primary emotions** are the adaptive responses to the frustration of a need: anger, sadness, fear, shame, joy, and the physical sensations that accompany them. They are "maladaptive" only when they are misdirected, excessive, or persistent.

**Secondary emotions** are the feelings that arise in the reaction to the primary ones, and they function to block the primary emotion's processing: guilt typically blocks anger, depression blocks anger and grief, shame blocks pride, and anxiety blocks the approach that the underlying need is demanding. The clinical target is very often the secondary emotion, because it is the secondary emotion that is generating the presenting complaint.

**Emotion schemes** are a generalisation from a specific emotional response, and they are the level at which the model locates the enduring vulnerability: "if I am not in control, I will be helpless"; "if I am rejected, I am worthless"; "if I fail, I am a failure".

**Emotional responses and their variations** — the way in which a particular emotion is expressed and experienced, which is a matter of the person's habitual response rather than of the emotion itself.

### 2.4 The position on the relation between emotion and cognition

The model is clear that **cognition and emotion are mutually determining** and that the direction of determination varies from person to person and from moment to moment. Some clients change when they think differently; others change when they feel differently; and many need both.

The clinical implication is diagnostic rather than theoretical: the practitioner must determine, for this client and at this point, which is the bottleneck. Greenberg's own phrasing is that the practitioner should ask whether the client's problem is primarily a thinking problem, a feeling problem, or a doing problem, and the answer determines the intervention.

## 3. The Change Point

### 3.1 The concept

The **change point** is the specific point in the processing of a core emotion at which the client is most likely to change, and it is the most distinctive technical contribution of the model. The concept is derived from the observation that clients are most amenable to change at a particular moment in the emotional process, and that practitioners who are not aware of the moment will either press too hard too early or press too softly too late.

**The change point is the moment when the client is experiencing the core emotion at its most, and is simultaneously able to remain present with it.** Before the change point, the client is either not in the emotion or is being protected from it by a secondary emotion. After the change point, the emotion has been resolved or has been abandoned in favour of a secondary emotion or a defence.

The change point is thus a narrow window, and the practitioner's task is to find it and to work in it.

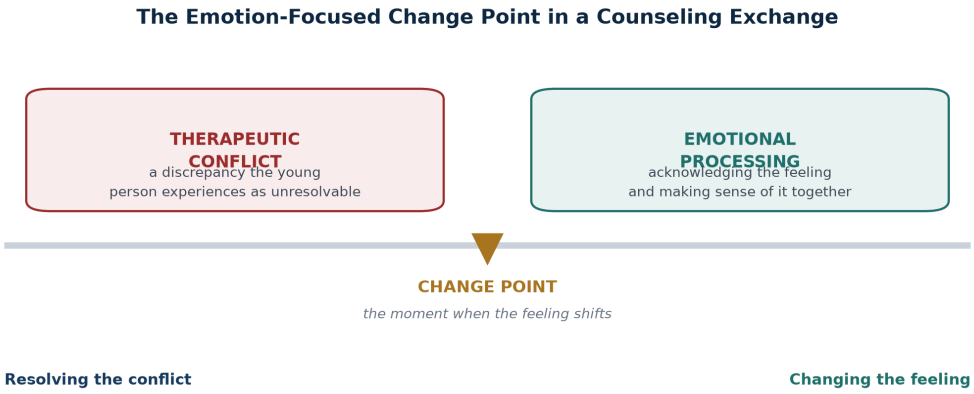

**Figure 37.26** The change point located within the arc of the emotional process, showing the primary emotion, the secondary emotion that blocks it, the point of maximum emotional arousal, and the resolution.

### 3.2 The two components

The change point has two components, and a practitioner who recognises only one of them will miss the moment.

**The emotional component** is the client's experiencing of the core emotion at its peak, with the associated physiological arousal, the facial expression, the voice quality, and the body posture.

**The cognitive component** is the client's accessing of the core appraisal — the meaning of the situation for the core need. The appraisal is what determines the emotion, and a client who is feeling the emotion at its peak but who has not accessed the appraisal is in a state of arousal without a meaning, and the state will be resolved by a secondary emotion or a defence rather than by a reorganisation.

The two components occur together in the moment of the change point, and a practitioner who produces the emotional component without the cognitive component has produced a discharge rather than a change.

### 3.3 The practitioner's task

The task is a sequence, and it is worth stating it as a set of steps.

**Identify the core emotion.** The work begins in the assessment, and the identification of the core emotion is one of the deliverables of the assessment phase.

**Find the blockage.** Almost always a secondary emotion, and the task is to identify it and to name it for the client.

**Work through the blockage.** The practitioner does this with warmth and with some assertiveness, and the standard move is to say what the practitioner thinks the client is feeling and to invite the client to consider it. This is where the "empty chair" and the "chair work" of the process stage becomes relevant.

**Achieve the change point.** The client is then helped to stay with the core emotion, and the practitioner supports the arousal, and the practitioner's own arousal and warmth are the instruments.

**Facilitate the resolution.** The resolution is not the end of the session; it is the beginning of the new emotional state, and the practitioner helps the client experience the solution emotion.

### 3.4 The emotional processing steps

The standard procedure for the processing stage has five steps, and a student should be able to name them.

1. **Attune and focus.** The practitioner attends to the core emotion, usually by reflecting it, and sometimes by exaggerating it, and the exaggeration helps to bring the emotion into focus.
2. **Confirm and clarify.** The practitioner confirms the emotion, sometimes by naming it directly, and the naming is a key moment, because a client who has never had their core emotion named by another person is being given a new experience.
3. **Congruence and the empathic stance.** The practitioner is present with the emotion rather than managing it, and this is the "being with" stance, and it is a demanding stance to hold.
4. **Facilitating the expression.** The practitioner encourages the expression of the core emotion, and the expression is the vehicle of the processing, and the practitioner matches the arousal.
5. **Reaching the resolution.** The emotion resolves, and the practitioner helps the client notice the new emotional state, and the noticing is essential, because the new state is the thing that will be available to them in the future.

## 4. The In-Session Emotion Coaching

The second major procedure, and the one most applicable to work with young people, is the **emotion coaching**, and it comes from a different research tradition — the work on parental emotion regulation with young children, and the body of research on the "emotion socialization" of children.

### 4.1 The procedures

**The empathic statement.** The practitioner reflects the child's or young person's emotional state in a statement, and the statement is a hypothesis that the young person can correct, and the correction is itself data.

**The emotion labelling.** The practitioner names the emotion, using a label from a list that is introduced gradually and is not pejorative. "Frustrated" is a safer first label than "furious", and "disappointed" is safer than "sad".

**The validation.** The practitioner validates the emotion by stating its legitimacy in the situation. The validation is of the emotion, not of the behaviour, and the distinction matters, and a practitioner who validates the behaviour has made an error.

**The problem-solving and the choices.** The practitioner helps the young person identify the problem, and then the choices. The order is important: the emotion is processed first and the problem-solving second, and reversing the order produces a young person who solves the problem without ever having been with the feeling that generated it.

### 4.2 The emotion coaching with parents

The most widely used application of the emotion coaching is with the parents of young children, and it is effective enough that a student should know it even if the population served is older. The structure is a hierarchy of responses to a child's distress: first, the parent is taught to **empathise** and to name the emotion; second, to **validate** the emotion; third, to **label** the emotion and set a limit on the behaviour if necessary; and fourth, to **problem-solve**.

The teaching is done with video-feedback where possible, and it is the first and the third steps that parents most often skip, and they are the steps that matter most.

### 4.3 The emotion coaching with adolescents

With an adolescent, the same procedure is used with two modifications, and the modifications are what make it usable.

**The developmental modification.** The adolescent is not told what the emotion is and is not told what to do; the practitioner labels and validates and then asks. The adolescent's own label is preferred, and the adolescent's own solution is required, because a solution supplied by an adult is a solution the adolescent will not use.

**The relational modification.** The emotion coaching is often best delivered through the parent, because the adolescent's capacity to be with their own emotions is being undermined by the parent's response to them. A young person whose mother's response to her distress is to become more distressed cannot learn to self-soothe, and the work with the mother is the prerequisite.

# 6. Emotion-Focused Work with Children and Adolescents

## 6.1 The developmental fit

Emotion-focused therapy is unusually well matched to the adolescent period, and a student should be able to give the reasons.

**Adolescence is the period of the highest emotional intensity in the human life course.** The affective neuroscience of the period is fairly consistent: the reactivity of the emotional system is at its peak, the regulation capacity is still developing, and the gap between the two is at its widest. A model that works directly with emotion is working with the adolescent's actual experience rather than around it.

**The developmental task of adolescence is the construction of a new self, and the emotions are the material.** The shame, the grief for the childhood, the anger at the limits, the anxiety about the future, the exhilaration of the first relationships — these are not symptoms. They are the content of the developmental work, and the model treats them as such.

**The adolescent's capacity to reflect on their own emotions is newly available.** The concrete operational stage of Piaget's sequence and the corresponding increase in metacognitive capacity mean that a young person at fourteen or fifteen can, in the right conditions, do the work the model asks. This is a substantially different picture from the child of eight, and it is why the model's adolescent adaptations are viable.

**Emotion-focused work is a good fit for the presentations that most often reach a school or community service.** The young person who is angry, who is ashamed, who is grieving, who is anxious, who cannot say what they feel, and who is in trouble — these are the presentations in which the model's core question is most directly useful: what is the core emotion, and what need has it arisen from?

## 6.2 The specific adaptations

**The assessment phase is longer and the targets are negotiated.** The model assumes an assessment in which the core emotion and the pattern are identified. With an adolescent, the practitioner should expect to spend two or three sessions on the assessment, and should be honest with the young person about the length, and should be explicit that the assessment is not a delay before the work but a part of it.

**The core emotion is often not the presenting emotion.** A young person who presents with anger may have a core emotion of shame, and a young person who presents with anxiety may have a core emotion of grief. The assessment's task is to get beneath the presenting emotion, and the presenting emotion is frequently the secondary emotion that is doing the blocking.

**The work with the parents is essential and is often the difference between success and failure.** This is the single most important developmental modification. The adolescent's capacity to be with their own emotions is being continuously undermined by the responses of the adults around them, and the work with the parents is a prerequisite for the individual work rather than an adjunct to it. A practitioner who works with a distressed adolescent in a household where the adults cannot tolerate the adolescent's distress is doing work that will not hold.

**The pace must be slower and the arousal lower.** The change point requires the client to sustain a high level of arousal, and a young person with a dysregulated nervous system — and many do — cannot sustain it, and pushing for the change point with a young person who is already at their limit produces a collapse rather than a change. The preparation phase of Chapter 40 is not optional for many of the young people who present.

**The resolution must be named and recorded.** The new emotional state at the end of the session should be explicitly noticed, and where possible written down, and a young person who has had a peak of distress followed by a moment of calm has had an experience that is worth keeping.

## 6.3 The presentations

Four presentations are particularly suited to the model.

**The young person with a chronic anger problem.** The anger is nearly always a secondary emotion blocking a primary emotion, usually grief or shame, and the treatment is to work beneath the anger rather

than to manage it.

**The young person with a physical presentation.** A young person who comes to the clinic with headaches, with abdominal pain, with a rash, with a sleep disturbance, and with no medical explanation, may be presenting a primary emotion in a somatic form, and the somatic work of Chapter 43 is the natural companion to this chapter.

**The young person with an eating presentation.** The emotion-focused model has been applied to both the restrictive and the bingeing presentations, and the eating behaviour is typically functioning to manage a primary emotion that the young person cannot otherwise tolerate.

**The young person with a relational problem.** The model's interpersonal procedure, in which a specific interaction with a significant other is imagined and worked through, is particularly useful with the young person whose difficulties are concentrated in a relationship with a parent, with a peer, or with a partner.

### 6.4 The limits

**The model requires the capacity to be with a feeling.** A young person with a very restricted range, with high dissociation, or with a severe and longstanding trauma response may not be able to access and sustain the core emotion, and the preparatory work of Chapter 40 must come first.

**The model can be experienced as a demand to feel.** A young person who has been told by adults to "calm down" for fifteen years may experience the invitation to sit with a feeling as another demand, and the practitioner should name this possibility in advance.

**The model can be experienced as the practitioner doing the emotional work.** The stance of "being with" the client's emotion is a demanding stance for the practitioner, and the practitioner who is managing their own distress rather than sharing it will be detected, and a young person will stop bringing the feeling.

## 7. Case Illustration: The Young Woman Who Was Always Angry

**Presentation.** Tia is fifteen, and the referral from school describes a young woman who is "aggressive with staff, swearing, and defensive". Her mother describes a young woman who "explodes over nothing" and who has become "a different person since her grandmother died in July". The school has had three exclusions.

**The first session.** The practitioner begins with the emotion coaching, not with the assessment, and the reason is that the assessment will not proceed with a young person who is in the state Tia is usually in.

The practitioner says: "I want to start with something simple. You've come in looking like you're ready to fight, and I wonder if that's actually about something else." Tia says, sharply: "It's about whatever you want to make it about." The practitioner reflects: "So it's about not being messed with." Tia says: "It's about being *treated*." And then, unexpectedly, she tells the practitioner that the school has been telling everyone she is a "problem" and that she has read the comments in the file, and that her own mother has said "you were exactly like your dad" and that her dad is in prison.

**The second session.** The practitioner returns to the anger. Tia says: "Everyone expects me to be angry, so I am." The practitioner asks what she is underneath it, and Tia says: "Tired." And the practitioner works with the tired for a while, and Tia says: "I am so tired of being the one that's wrong, and I can't even be sad about

Gran because then I'm the one who's sad and everyone's got enough."

**The assessment.** Over the next two sessions, the practitioner works on the assessment, and the assessment identifies the pattern with a precision that surprises Tia.

The core emotion is **grief**, for a grandmother who died in July after a long illness, and Tia had been the primary carer, having spent most of her fifteenth year in hospitals and at her grandmother's bedside.

The secondary emotion is **anger**, which is what Tia has been presenting, and the anger has been blocking the grief, and the anger has been doing two things: it has kept Tia from having to feel the grief, and it has been the only available response to a set of situations in which Tia is treated as the problem — including, most significantly, by her own mother, whose grief for her own mother has been expressed as anger at Tia.

The appraisal at the change point is the meaning of the loss: that the people she cared for are taken, and that nobody has asked her about it, and that being angry is the only way she has found to be listened to.

**The intervention.** Four elements.

*Element one: the reframe for Tia.* The practitioner does this explicitly and in a direct way: "The anger isn't the problem. The anger is what you have been doing instead of the grief, and it is the only way you have found to get anybody to listen. And I want to say something else, which is that the things people have said to you — the comments in the file, your mum saying you're like your dad — those are not descriptions of you. Those are them not knowing what to do with a young woman whose gran died."

*Element two: the work with the mother.* This is the part of the plan on which the outcome will turn, and it is the hardest. The practitioner sees the mother alone, and the mother's account is that she has been "strong for Tia" and has not cried in front of her. The practitioner asks the mother about her own mother, and the mother cries, and the practitioner stays with her, and this is the first time anyone has asked the mother about her own loss. The specific change requested of the mother is: to stop the comparison with Tia's father entirely, and to tell Tia once, directly, that she is grieving too, and to stop asking Tia to be "strong" or "the strong one".

*Element three: the emotional work with Tia.* The practitioner works toward the change point over two sessions, with the preparation work of the previous sessions doing the work of establishing that Tia can stay with a feeling. The peak arrives in the fourth session, when Tia says, in a voice the practitioner has not heard from her: "I miss her. I miss her so much and nobody will let me say it because they all think I'm angry." The practitioner stays with her, does not interrupt, and does not reassure, and Tia cries for a long time, and at the end of the session Tia is quiet, and the practitioner asks what she is noticing, and Tia says: "I think I'm just tired, but it's a different tired to before."

*Element four: the school.* The practitioner writes to the school with Tia's agreement, and the letter is short and it says that Tia is grieving, that the exclusions are not helping, and that the school could be part of the treatment by allowing Tia to be absent for two days for the funeral that Tia was not permitted to attend. The school agrees, and Tia attends the funeral, and the practitioner does not overstate the significance of this, because Tia is not yet over anything.

**The outcome.** Over the following two months, Tia has one further exclusion, which follows an incident in which a younger student made a comment about her grandmother. Tia's mother tells the practitioner that they have been to the cemetery together twice. The school reports that Tia is engaging in lessons. The anger has not gone, and the practitioner says clearly that it is not expected to go, and that what has changed is what it is for.

**The interpretation.** The case illustrates the model's central technique. The presenting emotion was not the core emotion; the core emotion was identified through the secondary; the change point required both the emotional and the cognitive components, and the practitioner had to build the conditions for the cognitive component — the appraisal that the loss meant and that nobody would listen to it — before the peak arrived; and the most important intervention was not with Tia at all but with her mother, whose grief and anger were sustaining the pattern. The model predicts that the individual work will not hold without the systemic work, and this is the model's most practically useful claim for work with young people.

# 8. Evidence and Research Support

## 8.1 The status of the evidence

Emotion-focused therapy has one of the better research bases in the psychotherapy literature, and the student should be able to describe its structure.

**The process research is the strongest part of the base.** The finding that emotional change in session predicts improvement, and that it predicts it better than cognitive change, has been replicated across a range of presentations and across a range of therapists, and it is one of the more robust process findings in the field.

**The controlled trials are good.** The randomised trials of emotion-focused therapy against cognitive therapy and against treatment as usual have reported significant effects, with the emotion-focused treatment at least equal to the cognitive treatment and sometimes superior, and the effect sizes are large.

**The brief treatment claim is supported.** The model was developed as a brief treatment, with a specified number of sessions, and the trials support the efficacy of the time-limited protocol.

**The evidence base is smaller than that of the cognitive and behavioural therapies**, and the reason is partly the difficulty of the fidelity measurement and partly the smaller number of practitioners.

**The adolescent evidence is limited.** Most of the research has been with adults, and the developmental adaptations have been developed largely from clinical experience and from the related emotion-coaching research with parents of young children. A student should be candid about this.

**The emotion coaching research base is good.** The parental emotion coaching research has a substantial evidence base for reducing the emotional dysregulation of young children, and the effects are mediated by the parents' own regulation capacity.

## 8.2 Limitations of the evidence

**The trials are mostly by the model's developers and their close colleagues**, and the allegiance effects are correspondingly large.

**The fidelity measurement is difficult**, and the procedures are detailed enough that delivery varies considerably.

**The adolescent and the clinical populations with the most complex presentations are under-researched.**

**The measure of emotion change in session is a judgement-based rating**, and the research on the predictive power of it is robust but the construct is not independent of the observer's expectation.

# 9. Strengths and Limitations of Emotion-Focused Therapy

## 9.1 Strengths

**It is direct and it is brief.** A specified number of sessions, a specified target, and a specified procedure are all things a young person can be told, and a young person who is tired of being talked at will often prefer it.

**It treats the emotion as data.** The model does not pathologise the feeling, and a young person who has been told that their anger is a symptom is often relieved to discover that the anger is a response.

**It is compatible with everything else in this book.** The emotion-focused work can be combined with behavioural, cognitive, systemic, attachment, and trauma-informed work, and the combination is often the most useful.

**It identifies the secondary emotion.** This is a genuinely useful clinical skill, and it applies well beyond this model: the presenting complaint is frequently not the target.

**It locates the need.** The move from "what is the problem?" to "what need is this emotion in service of?" is one of the most useful questions a practitioner can ask, and it is applicable in almost any context.

## 9.2 Limitations

**It requires a capacity that some young people do not have**, and the preparatory work it assumes is not always done.

**The model is under-specified in its account of the emotional system.** It is a clinical model of emotion rather than a developmental or a neurological one, and a student who wants the latter should read the affective science.

**It can be experienced as a demand to feel.** The work with the emotion has to be prepared for and negotiated.

**The research base is narrow.** The adolescent evidence in particular is thin.

**It is vulnerable to practitioner error.** The procedures are simple and the pitfalls are not.

# 10. Cultural and Ethical Considerations

## 10.1 Culture and the expression of emotion

The model's account of emotion is universalist, and a student should be able to state where it is culturally bounded.

**The expression of emotion is culturally regulated.** In many cultures, particular emotions — anger, in particular, and in some contexts sadness and grief — are subject to strict regulation, and the display of them brings consequences. A young person from a family in which the expression of anger is dangerous will not access the anger in the consulting room, and the practitioner who works toward the change point regardless will produce a young person who complies in the room and shuts down outside it.

**The display rules differ and the practitioner must learn them.** The rules about what may be expressed, to whom, and in what form are learned early and are enforced by the family and the community. The practitioner's task is to establish them before the work, and the question to ask the family is not "how does

this young person express anger?" but "what happens in your family when someone is angry?"

**The categories of the model are themselves culturally patterned.** The taxonomy of the primary, secondary, and solution emotions was developed in a specific clinical culture with a specific repertoire of expressed affect, and the mapping of a young person's experience onto it requires a translation, and the translation should be done with the young person rather than to them.

**Grief and its rituals.** The model works with grief, and the rituals of grief are culturally determined and often specific, and a young person whose family's mourning practice is elaborate and public will need the practitioner to work within it rather than to substitute a Western individual process.

## 10.2 The politics of the model

The model is individual. The central question — "what emotion is this, and what need is it in service of?" — locates the difficulty in the young person's own emotional life, and a practitioner who asks it relentlessly can inadvertently individualise a difficulty that is produced by the young person's circumstances.

The correction is straightforward and the practitioner should be able to state it: **the need is real and the response of the environment to the need is also part of the picture.** A young person whose need for safety is frustrated by a school that is unsafe is not to be helped by processing the emotion; she is to be helped by the school becoming safe. A young person whose need for a stable home is frustrated by unstable housing is not to be helped by attending to the grief.

## 10.3 Ethical considerations

**The consent to the work.** A young person should know what the treatment involves, including that the practitioner will be asking them to stay with difficult feelings, and this should be said in advance.

**The regulation of the arousal.** The change point requires a high level of arousal, and a young person with a dysregulated nervous system, with a seizure disorder, with a cardiac condition, or with a history of an overwhelming response needs the preparatory work of Chapter 40 first, and the practitioner must screen for this rather than discover it in the session.

**The limits of the practitioner.** The "being with" stance is a demanding one, and the practitioner needs their own support and their own regulation, and a practitioner who is dysregulated will dysregulate the client. This is a supervision matter and it is a matter of professional self-care.

**The relationship with the parents.** The work with the parents must be transparent to the young person, and the boundaries between what is shared and what is not must be explicit, and the young person must be told what is said about them.

**The prohibition on the emotional pressure of the practitioner.** A practitioner who is Determined to reach the change point in a particular session is applying pressure, and the pressure is a form of coercion, and it can produce a compliance that is not a processing.

**Confidentiality and the disclosure of the core emotion.** A young person may disclose a core emotion in a session that the practitioner shares with the parents, and the disclosure is the treatment, and it must be protected.

# 11. Key Terms

## Key Terms at a Glance

- **Emotion-focused therapy** — The brief, structured treatment developed by Greenberg and colleagues in which the client's emotional experience is the primary datum and the focus of the work.
- **Emotion as the primary datum** — The model's foundational claim that emotion, rather than cognition, behaviour, or the relationship, is the primary object of the work.
- **Emotion as a response to a need** — The account in which the primary emotions are organised in relation to the needs for secure attachment, autonomy, control, approval, worth, connection, and identity.
- **The needs framework** — The seven needs in relation to which the primary emotions are organised, and the clinical question of which need a given frustration has activated.
- **Emotion as adaptive** — The proposition that every emotion serves a purpose, and that the problematic emotions are misdirected, excessive, or aimed at the wrong target.
- **Primary emotions** — The adaptive responses to the frustration of a need: anger, sadness, fear, shame, joy, and the sensations that accompany them.
- **Secondary emotions** — The feelings that arise in the reaction to the primary ones and that function to block the primary emotion's processing: guilt, depression, shame, and anxiety.
- **The blockage** — The secondary emotion that prevents the processing of the core emotion, and the usual target of the work.
- **Emotion schemes** — A generalisation from a specific emotional response, and the level at which the model locates the enduring vulnerability.
- **Solution emotions** — Pride, confidence, calm, and the sense of the other as a potential ally, understood as the forms of emotional transcendence.
- **Emotional transcendence** — The highest form of emotional life, in which the self is expanded beyond the narrowness of the immediate situation.
- **The change point** — The moment in the processing of a core emotion at which the client is most amenable to change, and the model's central technical contribution.
- **The two components of the change point** — The emotional component, the experiencing of the core emotion at its peak, and the cognitive component, the accessing of the core appraisal.
- **The core appraisal** — The meaning of the situation for the core need, which determines the emotion and which must be accessed for a change to occur.
- **The emotional processing steps** — Attune and focus, confirm and clarify, the empathic congruence, facilitate the expression, and reach the resolution.

**Key Terms at a Glance (continued)**

- **The "being with" stance** — The practitioner's congruent presence with the client's emotion rather than its management.
- **Emotion coaching** — The procedure of empathising, labelling, validating, and then problem-solving with the client, and the strategy of doing so with parents of young children.
- **The empathy step** — The practitioner's empathic statement of the client's emotional state, offered as a hypothesis the young person can correct.
- **The labelling step** — Naming the emotion with a non-pejorative label, introduced gradually.
- **The validation step** — Stating the legitimacy of the emotion in the situation, and of the emotion rather than the behaviour.
- **The problem-solving step** — Identifying the problem and then the choices, and the requirement that it come after the emotion is processed.
- **The parental emotion coaching hierarchy** — Empathise, validate, label and limit, and then problem-solve.
- **The thinking, feeling, and doing question** — The diagnostic question of whether the client's problem is primarily a thinking, a feeling, or a doing problem, and the intervention it determines.
- **The focus of attention procedures** — The set of techniques in which the client is guided in attending to a particular aspect of their internal experience.
- **The intrapersonal technique** — The processing of the client's experience of their own emotion in the presence of the practitioner.
- **The interpersonal technique** — The processing of a specific interaction with a significant other, imagined and worked through in the session.
- **The preparatory phase** — The work on regulation and stabilisation that must precede the processing phase for a young person with a dysregulated nervous system.

## 12. Chapter Summary

Emotion-focused therapy is a brief, structured treatment in which the client's emotional experience is the primary datum, and its founding observation — that clients change when they can identify, experience, and express their core emotions — was a direct response to the failure of the cognitive therapies with clients whose difficulties are not in their thoughts. The chapter traced the two foundations, the research programme in British Columbia that identified in-session emotional change as the best single predictor of improvement, and the reasons for the model's relatively limited clinical adoption, which are instructive: the requirement for a capacity to access feeling, the requirement for trained practitioners, and the under-specification of the account of emotion.

The core principles were developed: emotion as the primary datum, with the other elements in its service; the four components of the model's account of emotion, as a response to a need, as adaptive, as tolerable and changeable, and as transcending; the categories of primary, secondary, and solution emotions and the

emotion schemes, with the observation that the clinical target is very often the secondary emotion because it is the secondary emotion that generates the presenting complaint; and the position on the mutual determination of cognition and emotion, with the practical diagnostic question of whether the problem is a thinking, a feeling, or a doing problem.

The change point was described in detail, with the concept, the two components, the practitioner's task as a sequence, and the five steps of the emotional processing. The critical technical point was made that a practitioner who produces the emotional component without the cognitive component has produced a discharge rather than a change.

The in-session emotion coaching was described with its four procedures and the parental hierarchy, and the two developmental modifications that make it usable with adolescents — the adolescent's own label and the adolescent's own solution, and the use of the coaching through the parent where the parent's response is undermining the adolescent's capacity.

The developmental fit was developed through the four reasons, and the specific adaptations were described: the longer and negotiated assessment, the identification of the core emotion beneath the presenting emotion, the essential work with the parents, the slower pace and lower arousal, and the naming and recording of the resolution. The four suited presentations and the three limits were given.

The case of Tia demonstrated the model. The presenting anger was identified as a secondary blocking a grief, the appraisal at the change point was the meaning of the loss and of not being listened to, the practitioner built the conditions for the cognitive component before the peak arrived, and the decisive intervention was with the mother, whose grief and anger were sustaining the pattern. The model's prediction that the individual work will not hold without the systemic work is its most practically useful claim for work with young people.

The evidence was presented with its structure: the process research is the strongest part of the base, the controlled trials are good, the brief treatment claim is supported, the parental emotion coaching research is good, and the adolescent evidence is limited and developed largely from clinical experience. The limitations were named.

The strengths and limitations were set out, with the strongest strengths being the directness, the brevity, the treatment of emotion as data, and the identification of the secondary emotion, and the principal limitations being the capacity the model requires, the under-specified account of emotion, the thin adolescent evidence, and the vulnerability to practitioner error.

The cultural analysis addressed the cultural regulation of emotional expression, the need to learn the family's display rules before the work, the cultural patterning of the model's own categories, and the cultural specificity of the rituals of grief. The politics of the model were addressed with the correction that the need is real and the environment's response to it is also part of the picture. The ethical requirements covered the consent to the work, the regulation of the arousal and the screening that it requires, the limits of the practitioner and the need for supervision, the transparency of the parental work, the prohibition on the emotional pressure of the practitioner, and the confidentiality of the disclosure of the core emotion.

## 13. Review and Discussion Questions

**Review and Discussion Questions**

1. Explain the clinical observation that produced the emotion-focused model and the failure of the cognitive therapies it responded to.
2. State the two intellectual sources of the model.
3. Explain the research finding that changed the field.
4. State the four reasons for the model's relatively limited clinical adoption.
5. State the model's foundational claim and explain what it does not mean.
6. State the four components of Greenberg's account of emotion.
7. Explain the needs framework and the clinical question it generates.
8. Distinguish primary from secondary emotions, and explain why the secondary is often the target.
9. Explain emotion schemes and the level at which the model locates the vulnerability.
10. Explain emotion as transcendence and the solution emotions.
11. State the position on the relation between emotion and cognition, and the diagnostic question it generates.
12. Define the change point and explain why the practitioner must find it.
13. State the two components of the change point and the consequence of producing only one.
14. Describe the practitioner's task in reaching the change point.
15. State the five steps of the emotional processing.
16. Describe the four emotion coaching procedures.
17. State the parental emotion coaching hierarchy and identify the two steps parents most often skip.
18. State the two developmental modifications that make the emotion coaching usable with adolescents.
19. State the four reasons the model fits the adolescent period.
20. State the six specific adaptations for young people.
21. Describe the four presentations for which the model is particularly suited.
22. State the three limits of the model with young people.
23. Describe the case of Tia and state the three features of it that generalise.
24. Summarise the status of the evidence and its four limitations.
25. State the five strengths and the five limitations of the model.
26. Explain the four cultural considerations for emotion-focused work.
27. State the correction required by the politics of the model.
28. State the seven ethical requirements for this work.

**Review and Discussion Questions (continued)**

## 14. Practice Activities

**Practice and Application**

### Activity 37.1 — The Secondary Emotion Audit (60 minutes, individual)

Take a real case from placement and write the presenting emotion, the possible core emotion, and the specific secondary emotion that is blocking the core one. Then write the evidence for each: what in the account supports the identification, and what would make you revise it. Then write the appraisal — the meaning of the situation for the core need — in one sentence in the young person's own words. The final step is the one that distinguishes the model from a general empathy exercise, and most students find it the hardest and the most useful.

### Activity 37.2 — The Emotion Coaching Rehearsal (60 minutes, triadic)

One student plays a nine-year-old who is furious because a friend would not share a toy; one plays the mother, who is herself at her limit; one observes. The mother practises the four-step hierarchy: empathise, validate, label and limit, problem-solve. The observer's task is to note which steps were skipped and to note the mother's own emotional state as she attempts each. The last observation is the important one, because it is what Chapter 40 and the parent work of Chapter 33 are for.

### Activity 37.3 — The Change Point Sequence (90 minutes, small group)

In groups of three, take a case and write out the full sequence to the change point: the core emotion, the blockage, the work with the blockage, the approach to the peak, the emotional component, the cognitive component, and the resolution. Then write the specific words the practitioner would use at each step. Then write what the practitioner would do if the young person did not reach the peak. The last part is the practical reality of the work, and it is the part that is least often discussed in the literature.

### Activity 37.4 — The Cultural Display Audit (60 minutes, individual)

Take a young person from a family whose emotional rules differ from your own and write the family's display rules: which emotions may be expressed, to whom, in what form, and what happens when the rules are broken. Then write what this means for the work: what the young person is likely to show in the session, what they are likely to withhold, and what the practitioner would need to establish before the change-point work. Then write the ethical implication. The exercise is the most direct preparation for the cultural work in Chapter 48.

## 15. Annotated Reading Pathways

**For the model.** Read Greenberg and Rice (2001) for the process work and Greenberg and colleagues (2003) for the clinical procedures, and read Greenberg (2015) for the contemporary statement.

**For the emotion coaching.** Read Cooper and Golan (2013) for the adolescent applications and the Gottman material for the parental work. The emotion coaching is the most practically usable element of the model and the easiest to learn.

**For the process research.** Read the studies on in-session emotional change and on the change point. The process research is what justifies the model and it is more convincing than the outcome trials.

**For the wider emotional science.** Read the affective neuroscience literature on the adolescent period and on the developmental trajectory of the emotional system, and read the developmental emotion regulation literature. The model is a clinical model and the science is what tells you when it is safe to use it.

**For the critique.** Read the critical accounts of the emotion-focused model's account of emotion and the evidence limitations, and read the cultural critiques of Western affect models. The model is more useful when its boundaries are known.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Emotion-Focused Therapy** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is greenberg's model of emotion regulation, the change point, and emotion-focused work with youth in distress. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is safety, regulation, emotion, memory, relationships, and paced therapeutic work. The mechanism to keep in view is how threat, arousal, avoidance, meaning, and relational safety shape what a young person can feel, remember, and learn. The characteristic professional risk is moving into traumatic material before stabilisation, confusing calm with shutdown, or making disclosure the price of care. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | "This account fits, partly fits, or needs changing." | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | "These goals are mine as well as the service's." | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | "I have a way to begin, not just an instruction." | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in stabilisation sessions, trauma-informed schools and services, caregiver work, and specialist treatment pathways, adapting dose and pace to development and state. | "The work is challenging but understandable and stoppable." | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | "This is not only something I do in a counselling room." | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | "A setback leads to inquiry, not blame." | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | "Adults are changing some conditions too." | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | "I can explain what helps and why." | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | "Ending is planned; I am not disappearing from care." | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.**

Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Amara is fifteen and is seen in a family support service for sleep disruption, irritability, and falling participation. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Amara's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Amara explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on safety, regulation, emotion, memory, relationships, and paced therapeutic work. The first intervention is deliberately modest. Amara chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Amara has approved.

At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Amara can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?

- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Emotion-Focused Therapy

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Emotion-Focused Therapy** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

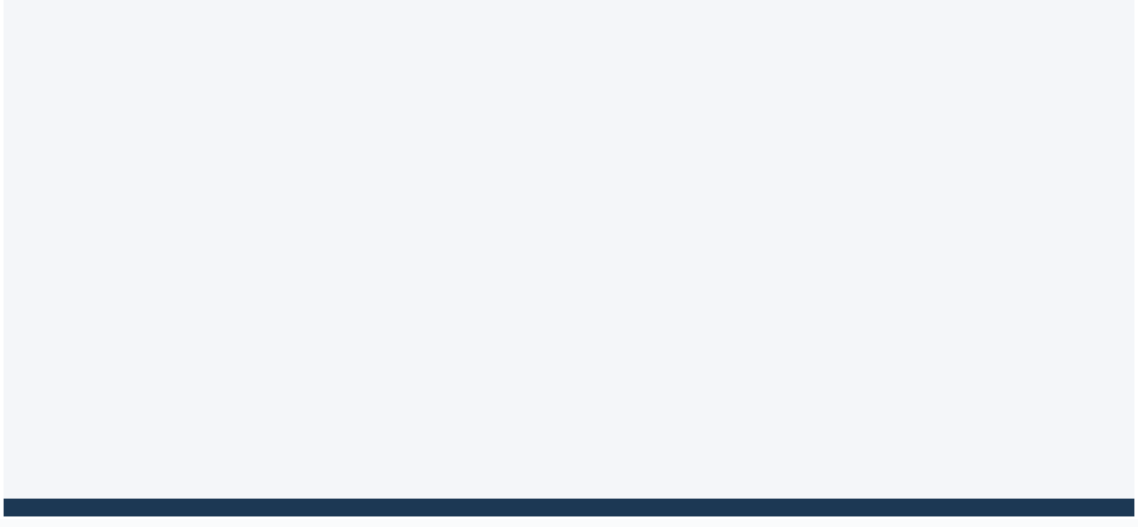
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Emotion-Focused Therapy** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider

disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Emotion-Focused Therapy**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Emotion-Focused Therapy to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 38

# Trauma-Informed Practice: Principles, Phases, and Precautions

The neurobiology of threat, the three-phase model, and the ethical floor rules of trauma work.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the development of the trauma-informed principle and describe the clinical and political context of its emergence.
- State the four core principles of trauma-informed practice and explain the operational meaning of each.
- Describe the threat response system, including the three states and their functions, and explain the clinical consequences of a dysregulated nervous system.
- Describe the three-phase model of trauma treatment and the clinical reasons for the phase structure.
- Apply the safety and the ethical precautions that govern work with a young person with a trauma history.
- Critically evaluate the trauma-informed principle, including the questions of the definition of trauma, of the risk of individualising a structural problem, and of the evidence for the phase model.

## Chapter Overview

The trauma-informed principle is not a therapy. It is a **stance**, and its most consequential feature is that it begins with the question of what has happened to a person rather than with the question of what is wrong with them. This is not a semantic preference. A service that asks what has happened will make different decisions about waiting lists, about the physical environment, about the involvement of a young person in decisions about their own care, about the behaviour of staff, and about the documentation of a young person's history.

The principle emerged from a specific convergence in the 1990s. Three developments made it possible. The **empirical** development was the accumulation of a large research literature on the neurobiology of traumatic stress, on the developmental consequences of chronic threat, and on the effects of adverse childhood experiences, which established beyond reasonable dispute that the experience of threat is itself a health event. The **clinical** development was the recognition that the therapeutic approaches to trauma had been developed for adults with single-incident trauma and were being applied to children with chronic developmental trauma, which is a different condition. The **political** development was the recognition, driven by the survivor movement and by the investigations into institutional treatment, that the systems which were supposed to treat trauma had frequently caused it.

The four principles are **safety**, **trustworthiness and transparency**, **peer support**, and **collaboration and mutuality** — and the fourth of these is the one most often confused with its opposite, because "collaboration and mutuality" means that the work is done *with* the young person, and a great many of the practices that are described as trauma-informed are in fact done *to* the young person.

This chapter presents the principles, the threat response system, the phase model, the precautions, and the critical analysis, which includes the serious question of whether the trauma frame can become a way of locating a young person's difficulties in their own history when the history has been produced by the institutions around them.

## 1. Historical Context

### 1.1 The history of the concept

The idea that a service should be organised around the understanding that many of the people it serves have been traumatised is not new in its content, but it is new in its scope.

The **early** history belongs to the veterans' and the disaster mental health services, in which the observation that the services themselves were retraumatising — through intrusive procedures, through the compulsory and unpredictable treatment, and through the environments — led to a first generation of trauma-informed principles, in the 1980s.

The **second generation** emerged in the 1990s from the children's services and from the foster care and adoption literature, and it was driven by the recognition that the children being placed in care had typically been traumatised by the very systems that then processed them.

The **third generation** is the current one, and it is largely the product of the **National Child Traumatic Stress Network** in the United States, which published a conceptual framework in 2005 and a practitioner toolkit, and which organised the field around the four principles. The framework is now the most widely used definition in the English-speaking world, and it has been adopted in national policy in several countries.

## 1.2 The four R's and the six principles

The National Child Traumatic Stress Network's framework is often summarised in the four R's — **recognise**, **respond**, **refer** — with a fourth, **re-educate**, added by others. The fuller statement is the **six principles** of the SAMHSA framework, which are:

**Safety.** Throughout the organisation, the physical and emotional safety of the people served is prioritised.

**Trustworthiness and transparency.** The organisation is clear about what it will do, and it is honest about what it cannot do.

**Peer support.** The organisation actively supports and links with the peer support available in the community.

**Collaboration and mutuality.** The organisation works with the people it serves, and the people it serves share power in the decisions.

**Cultural, historical, and gender issues.** The organisation recognises and responds to the cultural, historical, and gender issues in the lives of the people it serves.

**Empowerment, voice, and choice.** The organisation honours the voice and the choices of the people it serves.

The four core principles are the first, second, third, and fourth, and the last two are usually treated as cross-cutting. A student should be able to state all six, and should be able to give an organisational example of each, because the principles are properties of the organisation and not only of the practitioner.

## 1.3 The developmental context

The developmental context is what makes the trauma-informed principle different in child and adolescent services than in adult services, and it is essential to understand.

**The developing nervous system is more plastic and more vulnerable.** The adolescent brain is in the middle of the second great period of synaptic reorganisation, and the period is one in which the stress response systems are highly reactive and the prefrontal regulatory systems are not yet fully mature. The

adolescent is therefore more affected by chronic threat and less able to modulate it.

**The "child is not a small adult" principle.** The approach of treating a child as an adult with a smaller body produced the cognitive behavioural therapies of the 1980s and 1990s applied to children, and it is now understood to be an error in the treatment of trauma. A child who has been abused does not have a distorted appraisal of a safe situation; the situation is dangerous.

**Trauma is not a single event but a pattern.** The diagnostic criteria of the DSM and the ICD were designed around the single-incident trauma of the adult, and the developmental trauma of childhood — chronic, relational, repeated, and occurring during development — produces a different presentation, and the "complex trauma" or developmental trauma framework of the 1990s was developed to describe it.

**The developmental impact is cumulative and is mediated by the presence of a safe adult.** The research on the developmental trauma literature has established that the single most important protective factor against the impact of developmental trauma is a consistent, responsive adult in the young person's life, and this is why the work with the caregivers is central to the treatment rather than ancillary to it.

# 2. The Threat Response System

## 2.1 The three states

The clinical vocabulary of trauma-informed practice is most easily taught through the description of the threat response system, and a student should be able to state the three states and their functions.

**The dorsal vagal state**, sometimes described as the immobilised or shut-down state. The functions are conservation and the shutdown of the system when fighting and fleeing are not available or are not effective. Its signs are the ones that are easily mistaken for defiance: the blank stare, the flat affect, the "nothing" answer, the failure to respond, the refusal to move, the dissociation, and in the young person, the appearance of not caring. It is important for a practitioner to know that this state is not a choice and is not an attitude, and that a young person in this state cannot be reasoned with, cannot be challenged, and cannot be engaged in any task.

**The sympathetic state**, the fight-or-flight state. The functions are mobilisation and the rapid preparation for action. Its signs are the increased heart rate, the shallow rapid breathing, the tremor, the increased muscle tone, the narrowed attention, the rapid speech, the raised voice, the agitation, and the inattention to everything that is not the perceived threat.

**The ventral vagal state**, the social engagement state. The functions are the maintenance of safety through connection, the moderation of the other two states, the capacity for calm, and the capacity for social engagement. Its signs are the settled affect, the steady voice, the eye contact, the capacity to receive comfort, and the capacity to think.

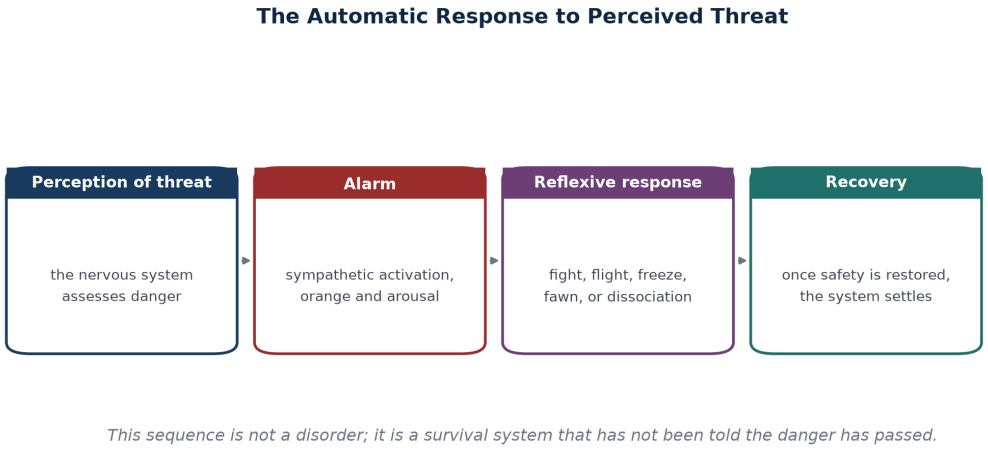


**Figure 38.27** The three states of the threat response system, showing the dorsal vagal, sympathetic, and ventral vagal states, their functions, and the characteristic signs of each.

## 2.2 The importance of the state for practice

The single most practically useful thing a practitioner can know about the threat response system is that **the client's state determines what intervention is possible.** A young person in the dorsal vagal state cannot be engaged in a cognitive task, a young person in the sympathetic state cannot be given an insight, and a young person in the ventral vagal state can do both.

A great many clinical failures with young people with trauma histories are failures of state, not failures of technique. A practitioner who tries to reason with a young person who has gone blank is not being skilful; the technique is unavailable.

The clinical rules that follow are simple and a student should be able to state them.

**If the young person is in the dorsal vagal state, the intervention is orienting and physical.** The voice is low and slow, the language is concrete, the focus is on the external environment, and the goal is to restore the ventral vagal state. Talking about feelings will not work and may make things worse.

**If the young person is in the sympathetic state, the intervention is containment and reduction.** The arousal is reduced before any content is addressed, and the reduction is done through the body — the breathing, the grounding, the movement — because the young person cannot be talked down from a sympathetic state.

**If the young person is in the ventral vagal state, the work can proceed.** This is the state in which the cognitive, the emotional, and the narrative work of this book is possible.

## 2.3 The window of tolerance

The **window of tolerance** is the range of arousal within which a person can function and in which information can be processed. Above it is the hyperaroused state; below it is the hypoaroused state. The developmental and clinical significance is that a young person with a trauma history has a narrow window, that the narrowing is itself a symptom, and that a good deal of what is called "non-compliance" in this population is a young person who has been pushed outside the window.

A practitioner working with a young person with a trauma history should be able to estimate the width of the window and should be working to widen it, because the widening is a precondition for everything else. The practical implication is that the preparatory and stabilisation work of Chapter 40 is not a preliminary to the treatment; it is a substantial part of it.

# 3. The Three-Phase Model

## 3.1 The structure

The three-phase model, which was developed principally from the work on complex trauma with adults and then applied to children and adolescents, divides the treatment into three phases with explicit criteria for movement between them.

**Phase one: safety and stabilisation.** The establishment of safety, in the broadest sense: physical safety, emotional safety, relational safety, and the practical safety of housing, income, and routine. The work is on the reduction of the symptoms, the establishment of the coping and grounding skills, the building of the relational safety with the practitioner, and the resolution of the practical problems that keep the young person in a threat state.

**Phase two: trauma processing.** The deliberate, consented, and carefully paced work on the traumatic memories and on the meanings attached to them. The phase includes the specific trauma-focused interventions — the protocols of Chapter 39 — and the narrative and meaning-making work.

**Phase three: integration and rehabilitation.** The consolidation of the changes, the rebuilding of the young person's life, the re-engagement with education, with relationships, with the future, and the development of the ordinary skills of a life that has been interrupted by the trauma.

## 3.2 The criteria for phase movement

The phase model's most practically useful feature is its explicit criteria for movement, and a student should be able to state them.

**The criteria to move from phase one to phase two** are: the young person is able to remain present in session and is not repeatedly dissociating; the young person can use the grounding and coping skills independently; there is sufficient relational safety in the therapeutic relationship; the practical situation is stable enough that the processing will not be interrupted by a crisis; the young person is able to tolerate the affect associated with the trauma narrative; and the young person has consented to the processing work, informed and ongoing.

**The criteria to move from phase two to phase three** are: the trauma narrative has been processed sufficiently that the memories are no longer intrusive or overwhelming; the young person has made a meaning of the experience that they can live with; the symptoms have reduced; the young person's functioning has improved; and the young person has developed enough coping to manage the ordinary stresses.

**The criteria to move backwards** are as important and are frequently forgotten: a return to phase one when the young person's functioning deteriorates, when the processing is reopened, or when a new crisis occurs.

## 3.3 The criticisms of the phase model

The phase model is the most influential framework in the field and it is also the most criticised, and a student should be able to state the criticisms.

**The evidence for the model as a package is thin.** The phases have not been tested as an integrated protocol in controlled trials. The evidence is for the components: the evidence for the specific trauma-focused interventions is good, and the evidence for the stabilisation skills is more limited.

**The phases can become a way of avoiding the difficult work.** A practitioner who is uncomfortable with the processing phase can keep the young person in phase one indefinitely, and the young person's compliance with the stabilisation work becomes the price of admission.

**The model under-recognises the developmental reality.** The phases presume a capacity for sustained processing that many young people do not have, and the developmental trauma literature argues that a young person's processing may need to be much more gradual and much more embedded in daily life.

**The model's universality is questionable.** The phase model was developed in a particular clinical culture, and the sequence assumes that safety can be established before the trauma is addressed, which is not always true, and which is not true in some cultural and political settings where the safety cannot be established by the individual or the practitioner at all.

# 5. The Precautions

## 5.1 The ethical floor

The precautions are the practical expression of the ethics of the work, and a student should be able to state them as rules.

**Do not force the disclosure of traumatic material.** The disclosure is not the treatment. The treatment is the young person's capacity to live with their history, and a young person who is pressed to disclose has been given a second experience of powerlessness over the very material that was taken from them. The consent to the processing phase must be explicit, informed, ongoing, and revocable.

**Do not use a trauma-focused intervention with a young person who is not stabilised.** The specific protocols — the EMDR of Chapter 39, the trauma-focused cognitive behavioural therapy — are contraindicated in an unstabled young person, and using them is a technical error with clinical consequences.

**Do not require the young person to remain in a session in which they are outside their window of tolerance.** The session is ended, and the ending is planned rather than improvised, and the young person is not left to manage their own dysregulation alone.

**Do not treat the disclosure of abuse as the goal.** The goal is the young person's safety, their development, and their functioning. A young person who has disclosed and who is safe and who is developing has been successfully treated, whatever they have or have not disclosed.

**Do not use the trauma frame to override the young person's own account of themselves.** A young person who says they are fine and who declines to describe their history has the right to say that, and a practitioner who insists is doing so in the name of the trauma.

**Do not make the disclosure a condition of support.** This is the requirement of the safeguarding framework, and a practitioner must know the local law and the local guidance, and must be clear with the young person at the outset what the limits of confidentiality are.

## 5.2 The clinical precautions

**Do not begin with the trauma narrative.** The first task is the history, the current functioning, the strengths, the resources, and the context, and the trauma narrative is a later task.

**Do not work with the memory before the affect can be tolerated.** A young person who cannot stay present in the room cannot process a memory, and the work on the tolerance comes first.

**Do not assume the timing.** The young person who has disclosed in week two has not begun processing, and the practitioner who mistakes a disclosure for a readiness to process will do harm.

**Do not work with a young person who is still in an unsafe environment.** A young person who is returning to a house in which the abuse continues cannot be in phase two, and the practitioner who works on the memory with such a young person has misunderstood the model.

**Do not neglect the body.** The trauma is in the body, and the somatic work of Chapter 43 is frequently the work that allows the cognitive and the narrative work to proceed.

**Do not neglect the caregiver.** A young person with a trauma history whose caregiver is not able to provide safety will not be helped by the individual work, and this is the most common reason for the failure of phase-based treatment with young people.

### 5.3 The organisational precautions

The trauma-informed principle is a property of the organisation, and a student preparing for practice should know what to look for in a service and what to advocate for.

**The physical environment.** Sight lines, exits, seating that does not put a person with their back to a door, the lighting, the noise, the privacy, and the absence of waiting in a queue with the people who triggered the referral.

**The front door.** Who is greeted, by whom, and what is said. A young person who has been referred by a school and who arrives to be questioned in a waiting room with the school's staff in it has been re-traumatised before the first session.

**The consent and the information.** A young person should be told, before the first session and in writing, what will happen, what will be confidential, what the limits are, and what their choices are.

**The staffing and the supervision.** A service that works with this population and does not have specific supervision of the staff is exposing the staff.

**The language of the organisation.** The language of the service's documents, of its letters to parents, and of its reports to a school is a trauma-informed practice question, and the language of a report about a young person who has disclosed abuse can determine the young person's future.

**The avoidance of retraumatisation in the systems.** A young person with a trauma history who is moved between four different professionals in a year has been subjected to a form of retraumatisation, and continuity is a clinical intervention.

## 6. Trauma-Informed Practice with Children and Adolescents

### 6.1 The developmental modifications

**Safety is established through the body before it is established through the relationship.** A young person who has been abused by adults will not feel safe in a room with an adult in it, however warm the adult, and the safety that is achieved first is the physical safety: the predictable routine, the door that is not locked, the knowledge of where the exits are, the reliability of the times, and the small, kept promises.

**The relationship is the treatment and it takes longer.** The relational safety with a young person with a developmental trauma history is not established in the first month, and the practitioner should be prepared for a period in which the young person is polite and formal and does not bring anything. The period is not a

failure of rapport; it is the young person testing, and the test is over months.

**The disclosure is a clinical event, not a milestone.** A disclosure should be met with a predictable, calm, and brief response, and the practitioner should have prepared what they will say in advance, because the young person will be watching the practitioner's face.

**The developmental impact is the target, not the memory.** A young person does not need to remember the event in order to be affected by it, and the treatment of the developmental consequences — the regulation, the attachment, the self-concept, the developmental tasks — is often the more important work.

**The work with the caregivers is central.** Where a young person remains with a caregiver, the caregiver's capacity to provide safety is the determinant of the outcome, and the practitioner who works only with the young person is working against the grain.

**The work is developmental in its tasks.** The trauma work with an adolescent includes the developmental tasks of Part V: the differentiation, the peer relationships, the identity, the academic engagement, and the future. A young person whose trauma is processed and who is then not helped to build a life will not stay well.

## 6.2 The presentations

**The young person with a chronic somatic presentation.** The somatic work of Chapter 43 is the entry point, and the somatic presentation is often the most legitimate and least frightening route into the treatment.

**The young person with a dissociation presentation.** The dorsal vagal state is the clinical fact, and the practitioner should be able to recognise it and should not attempt to work with the content while the young person is in it.

**The young person with an attachment-based presentation.** The attachment work of Chapter 34 and the mentalisation work of Chapter 42 are the natural approaches, and both are compatible with the trauma work.

**The young person with an eating presentation.** The family-based approach and the emotion-focused work of Chapter 37 are both relevant, and the somatic and the trauma work may be necessary.

**The young person in a care placement.** The placement is the trauma, and the clinical task is the stability of the placement and the availability of a consistent adult.

## 6.3 The specific working with young people who have been sexually abused

This presentation requires its own rules, and a student should know them.

**The assessment of the safety is the first and the most important task**, and it is ongoing.

**The parent's role must be established explicitly**, because the parent may be the perpetrator, and the practitioner must know which before the work begins.

**The do-not-contact orders and the supervision plans** are the framework in which the work is done, and the practitioner must understand them.

**The young person's own account of the abuse is not the only evidence and does not need to be complete.** The clinical work does not require the young person to have told the story in detail, and the pressure to disclose a detailed narrative is a pressure that the ethical frameworks explicitly reject.

**The behavioural manifestations must not be over-interpreted.** A young person who is hypervigilant, who is intrusive, who has sexualised behaviour beyond what is age-typical, who is oppositional, or who is enuretic, is presenting a set of responses to an abnormal environment, and the responses are not evidence of the young person's character.

**The father's role** requires particular care, and the professional position is that the involvement of a non-offending parent is generally beneficial and the exclusion of a non-offending parent is generally harmful, subject to the specific facts of the case and the local law.

## 7. Case Illustration: The Boy Who Could Not Be in the Room

**Presentation.** Samuel is twelve and is referred by a school safeguarding lead after a disclosure made to a teaching assistant about a stepfather. He has not been in school for eleven weeks. The referral states that he is "non-compliant with school attendance" and that his mother is "not engaging".

**The first contact.** The practitioner does not make the first contact by telephone with the mother. The first contact is a letter to the mother, and the letter says what the practitioner can and cannot do, and it says that the practitioner will also be writing to Samuel, and that the practitioner would like to speak with Samuel directly and separately. This is a standard and important procedural point: the young person is contacted directly and is not dependent on the adult who may be implicated.

**The direct contact.** Samuel does not respond to the letter, and the practitioner does not press. Three weeks later, a letter arrives, handwritten, containing four words: "I don't want to talk." The practitioner treats this as communication rather than as refusal, and the reply is short: "That's okay. I won't ask you to talk about anything you don't want to. I would like to meet you somewhere you feel okay, and to know what would help. You can reply to this letter with anything, or with nothing."

**The first meeting.** Samuel comes, with his mother, and the practitioner arranges the meeting in a room that is not the clinical room: a small room in the community centre with a window and a door that is not locked, and two chairs at an angle rather than across a desk. The practitioner says at the outset: "I am not going to ask you about your stepfather. Not today and not unless you want to. I am going to ask you about your week, and about what would make school better, and about what you need. You can stop at any time, and we can stop the whole thing, and if you stop, that is not a problem."

Samuel's dorsal vagal state is evident: he is flat, he is monosyllabic, and he does not look at the practitioner. The practitioner does not attempt rapport. She asks about the walk to the community centre, and the answer is that the walk is twenty minutes and he comes alone. The practitioner asks what he sees on the walk, and he names three specific things. The work in this session is entirely orienting, and the practitioner does not attempt any of it, and the session is twelve minutes long, and it ends with a specific arrangement: the same time and the same place next week.

**The phase one work.** The next three months are phase one, and the work is unglamorous and is the work that makes everything else possible.

**The physical safety.** A written safety plan, with the specific details of who Samuel lives with, when he is with whom, and what happens if his stepfather is in the house. The plan is shared with the safeguarding lead and with the mother's social worker, and the practitioner asks the mother directly, in a way that is careful and clear, whether Samuel's stepfather lives in the home. The mother says that he does not, and the

practitioner asks what the arrangement is, and the mother says that he comes on Sundays, and the practitioner asks whether Samuel is ever in the house on Sundays, and the mother says that Samuel stays at his grandmother's on Sundays, and the practitioner asks who arranges that, and the mother says that she does. The practitioner makes no judgement and records the account and continues.

**The practical problems.** The school attendance. Samuel has not been in school for eleven weeks and the referral calls this non-compliance. The practitioner asks what school was like before the referral and finds that Samuel was a good attender until the week of the disclosure, and that the school has not contacted him since. The school has done nothing. The practitioner discovers that the form tutor did not know what had happened and did not know that Samuel was distressed, and the practitioner makes the case to the school for a reintegration plan with a named adult, and the school agrees, and the first step is that Samuel comes to the school for one period with his form tutor, and the school is told that the "non-compliance" label is to be removed from the record and replaced with "ceased attendance following a safeguarding referral", and the school agrees.

**The grounding and the stabilisation.** The grounding work of Chapter 40 is taught explicitly, in the sessions, and it is taught as a set of practical skills for a twelve-year-old. The emotional regulation skills are taught before the disclosure work and are taught to the mother as well.

**The relational work.** The sessions are the same time and the same place, and the practitioner reliably turns up, and for six weeks Samuel says almost nothing beyond single words, and the practitioner does not fill the silence and does not comment on it. In the seventh week Samuel says, without preamble: "There's a thing on Sundays." The practitioner says: "Okay." And he tells the practitioner, over the following four sessions, what happens on Sundays, and the practitioner does not stop him, and the practitioner does not ask questions, and when he finishes the practitioner says: "Thank you for telling me. That was hard to say." And nothing else.

**The work with the mother.** The practitioner's work with the mother is the necessary work, and it is the work that most affects the outcome. The mother is shown the "what is your child worried about" material, and she is taught the grounding skills, and the practitioner asks her the question that the whole case turns on: "What did you think was happening on Sundays?" And the mother says, after a long silence: "I thought he was just being difficult." And the practitioner says: "He was telling you something. He was trying to get you to notice." And the mother cries, and the practitioner stays with her, and the mother's relationship with the safeguarding system — and with the practitioners who have been involved — is repaired a little, and the mother's participation in the plan changes entirely.

**The outcome.** At six months, Samuel is back in school four days a week, has a named adult at school, is seeing his grandmother on alternate Sundays with his mother, and has a written safety plan that he helped to write. The stepfather has not had contact with him. The mother is engaged with the social worker and with the practitioner. The trauma processing work has not yet begun, and the practitioner says clearly that it may not be needed in the form the phase model assumes, and that the work has been the building of a life that is not organised around the secret.

**The interpretation.** The case illustrates the trauma-informed principle in its pure form. Nothing in it was a trauma-processing intervention. The interventions were: the direct contact with the young person; the removal of the "non-compliant" label from the record; the addressing of the school's failure to re-engage him; the explicit safety assessment; the building of a predictable, bodily, non-verbal relational safety; the work with the mother, which was the decisive intervention; and the careful, unhurried reception of the disclosure when it came. The young person was never asked to talk before he wanted to, and the disclosure

that eventually came was the result of eleven weeks of predictability, not of a technique.

# 8. Evidence and Research Support

## 8.1 The status of the evidence

**The evidence for the individual components is good.** The specific trauma-focused protocols — the trauma-focused cognitive behavioural therapy and the EMDR — have strong evidence bases, and the first is the best-evidenced treatment for the trauma symptoms of children and adolescents.

**The evidence for the phase model as an integrated package is thin**, and a student should be candid about this. The phases have not been tested as a package in controlled trials.

**The evidence for the stabilisation skills is more limited and more developmental.** The grounding and the stabilisation work of Chapter 40 has a smaller and more recently developed evidence base, and the strongest evidence is for the general principle that the reduction of arousal precedes the cognitive work.

**The evidence for the trauma-informed service-level reforms is largely indirect**, and the field has relied on the plausibility of the principles, on the plausibility of the mechanisms, and on the consistent finding that the reforms improve the experience of service users and the well-being of the staff.

**The evidence for the principles themselves is now much stronger than it was.** The large studies of the health and educational outcomes of adversity, and of the dose-response relationships between the number of adverse experiences and the outcomes, and of the protective effect of a stable adult, have given the principles their epidemiological foundation, and a student should know the shape of this evidence even though the principles are not themselves interventions.

**The evidence for the specific model of the Attachment and Biobehavioral Catch-up and the CFTSI is good**, and the video-feedback mechanism is understood.

## 8.2 Limitations of the evidence

**The heterogeneity of the interventions makes the meta-analytic findings difficult to interpret**, and the pooled effects conceal substantial variation.

**The samples are dominated by the children of the adoptive or foster care system**, and the young people who are in the general population and who have been exposed to community violence, to domestic violence at a level that does not trigger a referral, and to the loss of a parent, are under-represented.

**The outcome measures are almost entirely symptom measures**, and the developmental outcomes, the educational outcomes, and the quality of life outcomes are much less well documented.

**The fidelity of the phased delivery is rarely measured**, and this is a significant weakness given that the phases are the model's principal mechanism.

**The long-term follow-up is limited**, and the developmental question — whether the gains are maintained into the adult years — is largely unanswered.

# 9. Strengths and Limitations of Trauma-Informed Practice

### 9.1 Strengths

**It starts with what happened.** The reorientation from the disorder to the history is the most important single change in the field's practice in forty years.

**It is developmentally sound.** The child-is-not-a-small-adult principle has corrected a substantial error.

**It has an evidence base of the right kind.** The epidemiological evidence is strong and the intervention evidence is good for the components.

**It is compatible with every other approach in this book.** A stabilisation phase is compatible with cognitive therapy, with the behavioural work, with the attachment work, with the mentalisation work, and with the somatic work.

**It has changed services.** The principle has influenced the physical environment, the front door, the consent procedures, and the language of the documentation, and these are not trivial changes.

**It has changed the professional self-conception.** The practitioner's role in this model is not primarily to interpret but to support.

### 9.2 Limitations

**It can individualise a structural problem.** This is the most serious criticism and it is addressed in Section 10.

**The definition of trauma is broad and contested**, and a framework that includes everything risks including nothing.

**The phase model can become a way of avoiding the work**, and the young person can be kept in phase one indefinitely.

**The model presupposes that safety can be established**, and in some circumstances it cannot, and the practitioner is then left without a model.

**The culture of the field has become strongly trauma-informed without a corresponding evidence base for many of its specific practices**, and the enthusiasm has sometimes outrun the technique.

**The risk of the "trauma narrative" becoming the young person's identity.** A young person who has been told for two years that they are a trauma survivor and who has been asked to tell the story repeatedly can acquire an identity organised entirely around the trauma, and this is the same error as the diagnostic identity and it is less visible.

## 10. Cultural and Ethical Considerations

### 10.1 The individualisation of a structural problem

The most serious ethical danger of the trauma-informed principle is that it locates the young person's difficulties in their history, and that this can be used, and is sometimes used, to explain away the conditions in which they live.

A young person who is in an unsafe school, who is in temporary accommodation, whose family is in poverty, who is being treated as a problem by the adults around them, and who has a history of a difficult event, does not need the history to be addressed first. The history is the reason the conditions are what they are, and the conditions are what the young person is currently living in, and the treatment of the conditions

is the treatment.

Three safeguards follow.

**Always ask what the young person is living in.** The question "what is happening in your life right now" is as important as "what happened to you", and it is more often actionable.

**Never let the trauma frame substitute for the structural one.** If the young person's difficulty is a product of the conditions, the conditions must be changed, and the frame of the work is a fight about those conditions and not a journey into the past.

**Keep the history in its place.** The trauma-informed principle does not require the trauma to be the centre of the treatment. In many cases the best work is the establishment of a good enough life in the present, and the young person may never need to process the memory at all.

## 10.2 Culture, trauma, and the meaning of the event

**The meaning of an event is culturally constituted.** The same event — a parent's violence, a community's response to a young person's behaviour, a sibling's death, a migration — means different things in different contexts, and a practitioner who applies a universal account of the traumatic event will misdescribe the young person's experience.

**Some events are not traumatic for the young person who experienced them.** The field's framing requires that the impact be assessed in the individual, and a young person who experienced a frightening event and was not frightened by it should not be given a trauma narrative to inhabit.

**The "trauma" of a community and a culture is a different order of thing** from the trauma of an individual, and the collective, historical, and political injuries of a community are not adequately addressed by an individualised model, and a young person whose community has been subjected to violence may be carrying a collective trauma that requires a collective response.

**Culturally specific healing practices** are frequently more available to a young person and more effective than the individual trauma work, and the practitioner should ask about them before assuming that the individual work is the route.

## 10.3 Ethical requirements

**Informed, ongoing, and revocable consent** to each phase and to each intervention within it.

**The young person as the decision-maker.** The principles require the voice and the choice of the young person, and this must be real rather than nominal, and the practitioner must be willing to accept a decision they disagree with.

**The avoidance of compulsory disclosure.** A young person who declines to disclose has the right to do so and has been treated well.

**The limits of confidentiality stated at the outset**, in writing, and the young person must know before they disclose what will happen.

**The avoidance of retraumatisation by the systems**, including the avoidance of unnecessary assessments, of repeated accounts, of unnecessary moves between professionals, and of intrusive procedures.

**The avoidance of the use of the trauma identity.** The young person's account of themselves is not to be replaced by a professional narrative about them.

**Cultural and historical humility.** The practitioner acknowledges the limits of their own framework and the existence of other frameworks in the young person's life.

**The obligations of the professional to the staff.** A service that works with this population has an obligation to supervise the staff and to care for their own dysregulation, and the neglect of this is a clinical error with clinical consequences.

## 11. Key Terms

**Key Terms at a Glance**

- **Trauma-informed practice** — A stance in which a service is organised around the understanding that many of the people it serves have been traumatised, and in which the question of what has happened precedes the question of what is wrong.
- **The four core principles** — Safety, trustworthiness and transparency, peer support, and collaboration and mutuality.
- **The six principles of the SAMHSA framework** — The four core principles plus the recognition of cultural, historical, and gender issues and the commitment to empowerment, voice, and choice.
- **The four R's** — Recognise, respond, refer, and re-educate.
- **Trauma-informed organisation** — The service-level reforms in the environment, the front door, the consent procedures, the staffing, and the language of the documentation.
- **Dorsal vagal state** — The immobilised or shut-down state, whose signs are easily mistaken for defiance and in which no cognitive or emotional work is possible.
- **Sympathetic state** — The fight-or-flight state, in which the arousal must be reduced before any content is addressed.
- **Ventral vagal state** — The social engagement state, in which calm and connection are possible and in which the cognitive, emotional, and narrative work can proceed.
- **Window of tolerance** — The range of arousal within which a person can function and in which information can be processed; above it is hyperarousal and below it is hypoarousal.
- **The narrowing of the window** — The developmental and clinical consequence of chronic threat, and the reason that the preparatory work is a precondition for the rest.
- **Developmentally traumatised** — The presentation produced by chronic, relational, repeated threat during development, as distinct from a single-incident trauma.
- **The three-phase model** — Safety and stabilisation, trauma processing, and integration and rehabilitation.
- **Phase one** — The establishment of safety in its broadest sense, the reduction of symptoms, the teaching of coping and grounding, the building of relational safety, and the resolution of practical problems.
- **Phase two** — The deliberate, consented, and carefully paced work on the traumatic memories and their meanings.
- **Phase three** — The consolidation of the changes, the rebuilding of the young person's life, and the re-engagement with education, relationships, and the future.

**Key Terms at a Glance (continued)**

- **The criteria for phase movement** — The explicit conditions for moving forward and for moving back, and the practical value of the backward criteria.
- **The ethical floor rules** — The prohibitions on forcing disclosure, on using a trauma-focused intervention with an unstabled young person, on requiring a young person to remain outside their window of tolerance, on treating the disclosure as the goal, and on overriding the young person's own account.
- **The single-incident and developmental trauma distinction** — The difference between the adult single-event model and the pattern that produces a different presentation in a child.
- **The developmental trauma criteria** — The criteria proposed for the developmental trauma category, and the debate about whether they belong in a diagnostic manual.
- **The dose-response finding** — The epidemiological finding that the number of adverse experiences is related to the range of health and educational outcomes, and that the relationship is graded.
- **The stable adult as a protective factor** — The single most important protective factor against the impact of developmental trauma, and the reason the work with the caregivers is central.
- **Retraumatisation by the systems** — The retraumatisation that occurs through repeated assessments, compulsory and repeated accounts, intrusive procedures, and unnecessary moves between professionals.
- **The trauma identity** — The risk that a young person who has been told repeatedly that they are a trauma survivor acquires an identity organised entirely around the trauma.
- **Collective trauma** — The historical, political, and communal injuries that an individualised model does not adequately address.
- **The practitioner as a container** — The role of the practitioner in holding the young person's arousal and affect, and the supervision and self-care that the role requires.
- **The five ways of noticing** — The clinician's attentional practice of noticing the young person's state before noticing their content.

## 12. Chapter Summary

Trauma-informed practice is a stance rather than a therapy, and its most consequential feature is that it begins with what has happened to a person rather than with what is wrong with them — a difference that changes decisions about waiting lists, physical environments, consent, staff behaviour, and documentation. The chapter traced the three developments that made the principle possible: the neurobiological and epidemiological research, the recognition that the adult-derived trauma treatments had been misapplied to children, and the political recognition that the systems treating trauma had frequently caused it.

The four core principles and the six-point framework were stated, with the observation that the fourth, collaboration and mutuality, is the one most often confused with its opposite, because much of what is described as trauma-informed is done to the young person rather than with them. The developmental context was developed: the plasticity and the vulnerability of the developing nervous system, the "child is not a

small adult" principle, the distinction between single-incident and developmental trauma, and the cumulative and mediated nature of the developmental impact.

The threat response system was described with the three states and their signs, and the clinically decisive point was made: the client's state determines what intervention is possible, and a great many clinical failures with this population are failures of state rather than of technique. The three clinical rules were stated for the dorsal vagal, the sympathetic, and the ventral vagal states, and the window of tolerance was described with the observation that the preparatory work of Chapter 40 is a substantial part of the treatment rather than a preliminary to it.

The three-phase model was described with its structure, its explicit criteria for movement in both directions, and its four criticisms, including the criticism that the phases can become a way of avoiding the difficult work and that the model presupposes a safety that cannot always be established.

The precautions were organised into the ethical floor, the clinical precautions, and the organisational precautions, and the organisational section is unusual in a chapter of this book in treating the principle as a property of the organisation rather than of the practitioner. The developmental modifications were described, with the direct contact with the young person and the parent's role as the two that are frequently got wrong, and the specific working with young people who have been sexually abused was treated in its own subsection with its own rules.

The case of Samuel demonstrated the principle in its pure form, and the practitioner never conducted a trauma-processing intervention. The interventions were the direct contact without the implicated adult as intermediary, the removal of the "non-compliant" label from the school record, the school re-engagement, the explicit safety assessment, the twelve-minute orienting first meeting, the grounding work, the unhurried reception of the disclosure when it came, and the work with the mother — which was the decisive intervention, and which was turned by a single question about what the mother thought had been happening on Sundays.

The evidence was presented with its structure: good evidence for the individual components, thin evidence for the phase model as a package, more limited evidence for the stabilisation skills, largely indirect evidence for the service-level reforms, and strong epidemiological evidence for the principles. The limitations were named.

The strengths and limitations were set out, with the individualisation of a structural problem identified as the most serious, and the trauma identity as the error that is less visible than the diagnostic identity and the same in kind.

The cultural analysis addressed the culturally constituted meaning of the event, the young person for whom the event was not traumatic, the collective and historical injuries that an individualised model does not reach, and the culturally specific healing practices that may be more available and more effective. The ethical requirements covered the consent, the young person as decision-maker, the prohibition of compulsory disclosure, the limits of confidentiality stated in advance, the avoidance of retraumatisation by the systems, the avoidance of the trauma identity, cultural and historical humility, and the obligations of the professional to the staff.

## 13. Review and Discussion Questions

### Review and Discussion Questions

1. Explain the three developments that made the trauma-informed principle possible.
2. State the four core principles and explain the operational meaning of each.
3. State the six principles of the SAMHSA framework.
4. Explain why "collaboration and mutuality" is the principle most often confused with its opposite.
5. Explain the developmental reasons why the trauma-informed principle differs in child and adolescent services.
6. State the "child is not a small adult" principle and the error it corrected.
7. Distinguish single-incident from developmental trauma and state the clinical consequence of the distinction.
8. Describe the three states of the threat response system and the signs of each.
9. Explain why the state determines the possible intervention, and state the three clinical rules.
10. Define the window of tolerance and explain its clinical significance.
11. Describe the three phases of the trauma treatment model and the content of each.
12. State the criteria for moving from phase one to phase two, and the criteria for moving backwards.
13. State the four criticisms of the phase model.
14. State the five ethical floor rules.
15. State the five clinical precautions.
16. State the six organisational precautions and explain why the principle is a property of the organisation.
17. State the six developmental modifications for work with young people.
18. State the rules for work with young people who have been sexually abused.
19. Describe the case of Samuel and state the four features of it that generalise.
20. Summarise the status of the evidence and its five limitations.
21. State the six strengths and the six limitations of the principle.
22. Explain the individualisation of a structural problem and the three safeguards.
23. Explain the three cultural considerations.
24. State the nine ethical requirements for trauma-informed work.

## 14. Practice Activities

### Practice and Application

### Activity 38.1 — The State Audit (90 minutes, field-based)

In a placement, observe a young person in three different settings and record, for each, their state: dorsal vagal, sympathetic, or ventral vagal. Record the physical evidence. Then record what the adults in each setting did in response. Most students find that the adults respond to the dorsal vagal state with the interventions that are appropriate to the sympathetic state, and the exercise is a more effective argument for the three-state model than any reading.

### Activity 38.2 — The Phase Placement (75 minutes, individual)

Take a case from placement and place the young person in one of the three phases, with the specific evidence for the placement. Then write the criteria: what would have to be true for them to move forward, and what would have to be true for them to move back. Then write the specific intervention that is indicated *now* and only now. The final step is the discipline of the model and it is the step that prevents the phases becoming a way of avoiding the work.

### Activity 38.3 — The Consent Conversation (90 minutes, pairs)

One student plays a young person who has disclosed and who is frightened of what will happen next; the other plays the practitioner. The practitioner must explain, in plain language, what will happen, what will be shared, with whom, and what the young person's choices are. Then reverse roles. The exercise is difficult and the difficulty is the point: most practitioners over-explain and under-inform, and the young person usually understands the first attempt better than the practitioner expects.

### Activity 38.4 — The Structural Audit (60 minutes, individual)

Take a case with a trauma history and write two accounts. The first is the trauma account: what happened, and what it produced. The second is the structural account: the housing, the income, the school, the family's circumstances, the community, the availability of a safe adult. Then write what proportion of the young person's current difficulty the two accounts explain, and write the interventions that follow from each. Then write the priority. The exercise is the most important one in the chapter and the one most often skipped in practice.

## 15. Annotated Reading Pathways

**For the principles.** Read the National Child Traumatic Stress Network's conceptual paper and the SAMHSA framework, and read the National Child Traumatic Stress Network's practitioner guide. These are short and they are the definitional documents.

**For the science.** Read van der Kolk (2014) for the neurobiological account, Porges (2011) for the polyvagal framework, and Siegel (2010) for the attachment and regulatory account. The three together are the theoretical basis of the practice.

**For the clinical model.** Read the Trauma-Focused Cognitive Behavioral Therapy manual and the EMDR manual, and read the child and family traumatic stress intervention manual. These are the specific protocols and they are more useful than the general accounts.

**For the developmental adaptation.** Read the developmental trauma literature and the work on the child-is-not-a-small-adult principle, and read the child advocacy centre model, which is a service-level application.

**For the critique.** Read the critical literature on the individualisation of structural problems, on the expansion of the definition of trauma, and on the trauma identity. The field's own self-criticism is essential and it is developing.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Trauma-Informed Practice: Principles, Phases, and Precautions** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is the neurobiology of threat, the three-phase model, and the ethical floor rules of trauma work. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is safety, regulation, emotion, memory, relationships, and paced therapeutic work. The mechanism to keep in view is how threat, arousal, avoidance, meaning, and relational safety shape what a young person can feel, remember, and learn. The characteristic professional risk is moving into traumatic material before stabilisation, confusing calm with shutdown, or making disclosure the price of care. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 7. Apply the method | Use the chapter's core procedures in stabilisation sessions, trauma-informed schools and services, caregiver work, and specialist treatment pathways, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support,

timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Jonas is fifteen and is seen in an integrated school and health team for conflict with parents about autonomy. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Jonas's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Jonas explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on safety, regulation, emotion, memory, relationships, and paced therapeutic work. The first intervention is deliberately modest. Jonas chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Jonas has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Jonas can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be

sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Trauma-Informed Practice: Principles, Phases, and Precautions

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Trauma-Informed Practice: Principles, Phases, and Precautions** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

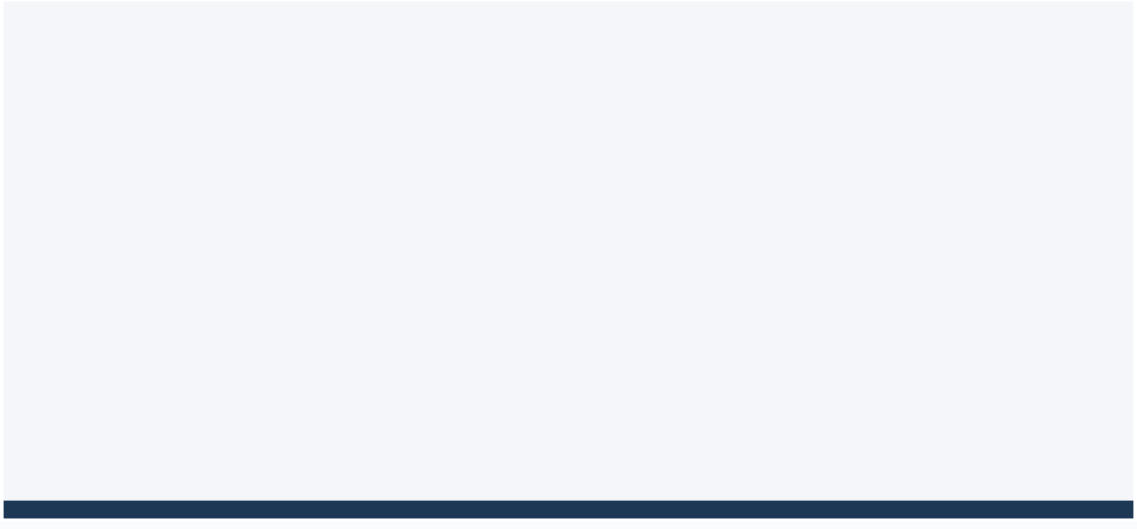
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Trauma-Informed Practice: Principles, Phases, and Precautions** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Trauma-Informed Practice: Principles, Phases, and Precautions**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a



discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Trauma-Informed Practice: Principles, Phases, and Precautions to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 39

# EMDR and Bilateral Stimulation

Shapiro's protocol, the adaptive information processing model, and careful adaptation for children.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the history of the eye movement desensitisation procedure and the development of EMDR, and state the evidence that led to the method's acceptance.
- State the adaptive information processing model and explain how it accounts for the efficacy of a procedure that was originally thought to be effective because of the eye movements.
- Describe the eight phases of the EMDR protocol and the bilateral stimulation methods.
- Explain the mechanisms proposed for the effect of bilateral stimulation, and evaluate the evidence for each.
- Describe the adaptations of EMDR for children and adolescents, including the specific modifications and the evidence for them.
- Critically evaluate the cultural and ethical dimensions of EMDR practice, including the questions of the acceptability of the procedure and of the treatment of the memory.

## Chapter Overview

In 1987, a psychotherapist working with a woman who was suffering from a disturbing memory noticed that she reported a reduction in the distress associated with the memory while moving her eyes from side to side. The observation was made with one patient, it was not a controlled experiment, and it was made in a context in which the prevailing assumption was that eye movements had no psychological effect whatsoever.

Twenty years later, the procedure was a first-line treatment for post-traumatic stress disorder in adults, it was endorsed in the guidelines of the major international bodies, and the underlying mechanism was the subject of one of the more consequential scientific controversies in the history of psychotherapy.

The story is worth telling carefully, because it illustrates a methodological point that the practitioner should take seriously: the eye movements were almost certainly not doing the therapeutic work, and the treatment is effective anyway. The contemporary understanding is that the bilateral stimulation is a **provocative technique** — an apparatus that reliably elicits and sustains the dual attention and the internal association that the treatment requires, and that the same work can be achieved by other means. The evidence for this has been gathered by a series of well-controlled studies comparing eye movements with other forms of bilateral stimulation and with a matched control condition, and the results are more consistent than the field's earlier polemics suggested.

For work with young people, the most important practical facts are these. The procedure with children is markedly different from the adult procedure, and the differences are not cosmetic. The **assessment and preparation phases are longer**, the young person is taught the technique themselves, the clinician is far more active, the **parent is in the room**, and the **body and the regulation work of Chapter 40 comes first**. The evidence for the paediatric protocol is good, and it is better than the evidence for most of the treatments in this book in the specific population with a specific disorder.

## 1. Historical Context

### 1.1 The origin

Francine Shapiro was working with a client who described a memory of an assault that she found unutterably distressing. In the course of the session, the client spontaneously moved her eyes from side to side, and reported, with some surprise, that the memory had become less vivid and less disturbing. Shapiro asked the client to do the eye movements deliberately, and observed a repeat of the effect.

Shapiro then developed the procedure as a systematic treatment, and the early papers described it in terms of a new kind of "information processing" in which the eye movements appeared to facilitate the "unblocking" of traumatic memories. The early formulations were not well specified, and the early trials were criticised, sometimes severely, for their methodology.

## 1.2 The controversy

The controversy was of a familiar and familiar-seeming kind. The critics' arguments were that the eye movements had no established physiological effect, that the method had been given a mystified theoretical justification, and that the early trials had used inappropriate controls. The proponents' arguments were that the empirical results were better than those of the competing treatments and that a mechanism was not a precondition of efficacy.

The field resolved the controversy in a way that is instructive. A series of well-controlled studies established several things: the **efficacy** of the procedure, which was not seriously in dispute even at the height of the controversy; the **specificity** of the bilateral stimulation, in that the procedure is more effective than a matched control that omits the eye movements; and the **absence of a specific mechanism**, in that the effect is found with several different forms of bilateral stimulation and with non-bilateral controls in some studies, which suggests that the stimulation functions as a device for sustaining a particular attentional state rather than as a treatment in its own right.

## 1.3 From eye movements to EMDR

The procedure was renamed and the theory was revised, and the shift is significant. The current model is the **adaptive information processing model**, which locates the pathology not in the memory but in the *failure to process* the memory, and the treatment in the *completion* of the processing. The bilateral stimulation is now understood as the element that elicits and sustains the associative processing while the memory is held in focus.

The renaming was not merely cosmetic. The change in the theory is a change in what the practitioner is doing: the clinician is not moving information out of the memory but is facilitating the patient's own processing of a memory that has not been completed.

## 1.4 The spread

The spread of EMDR into clinical practice has been remarkable, and it has been driven less by the mechanism debate than by three things: the treatment is brief, the guidelines recommend it, and it works. It is now used for post-traumatic stress disorder, for the phobias, for the obsessive-compulsive disorder, for the panic disorder, for the specific phobias, for the grief, and — increasingly, in the paediatric literature — for the specific procedural and accidental trauma of childhood, which is a considerably better fit for the paediatric protocol than the developmental trauma is.

# 2. The Adaptive Information Processing Model

## 2.1 The central claim

The model's claim is that **memory, once encoded and integrated into the general network of autobiographical knowledge, is permanently available for use and for change, and that many pathological conditions are the result of a failure of this processing**.

The implication is that the pathology is not in the content of the memory. The memory is accurate; it happened; the young person was in a car accident and the memory of the car accident is correct. The pathology is in the *storage* of the memory — in the fact that it has remained in a form in which it is experienced as a current event, in which it is accompanied by the physiological response that accompanied the original event, and in which it is not linked into the network of the rest of the person's life.

## 2.2 The components of the model

**The unprocessed memory.** A memory that has been encoded and stored in a form that remains vivid, that is experienced in the present tense, that is associated with the original autonomic and muscular response, and that is disconnected from the general narrative of the person's life.

**The dysfunction.** The symptoms are the consequence of the unprocessed memory: the intrusive images, the nightmares, the avoidance, the hyperarousal, the negative beliefs about the self and the world that the memory has generalised into.

**The link.** The missing element is the *link* between the unprocessed memory and the rest of the person's autobiographical knowledge. When the memory has been linked — when the young person can place it in a narrative of a life in which the accident is one event among many, in which it is over, and in which it is not the whole of who they are — the symptoms reduce.

**The bilateral stimulation.** The device that elicits and sustains the associative processing while the memory is held in focus.

## 2.3 The model and the treatment's logic

The treatment follows directly. The young person is asked to hold the image of the memory in focus while the bilateral stimulation is delivered, and to follow the eye movements wherever they lead, and to report whatever comes. Over the course of the processing, the memory changes: it becomes less vivid, the autonomic response diminishes, and the young person begins to report new associations, some of them painful and some of them neutral and some of them about the present rather than the past.

The final stage, the **installation** of the new associations, is the point at which the change becomes durable, and the installation is done by the clinician rather than by the young person, and it is a distinctive and often under-taught element of the procedure.

# 3. The Eight Phases

## 3.1 The phases

The protocol has eight phases, and a student should be able to name all eight and say what each is for.

**Phase one: the history and the stabilisation.** A full history, including the trauma history, the current symptoms, the medical and the psychiatric history, the developmental and the social history, the current resources, and the current level of functioning. The purpose is to establish that the young person is sufficiently stabilised to proceed and to establish the baseline against which the change will be assessed. A student should be able to state the criteria in Chapter 38 for this phase, because the EMDR history phase is a phase one in the phase model.

**Phase two: the preparation.** The preparation of the young person for the procedure itself: the explanation of what will happen, the establishment of the bilateral stimulation method, the teaching of the "internal focus of attention" and of the "external focus of attention" as cognitive anchors, the checking of the capacity to stay in the window of tolerance, and — for the paediatric protocol — the involvement of the parent.

**Phase three: the assessment.** The measurement of the subjective units of disturbance (the SUD), the body sensations, and the vividness of the image, for the selected memory, and the establishment of the baseline values that will be tracked through the processing. The clinician identifies the specific memory that will be worked on, and the choice of the memory is a clinical judgement and not a neutral matter.

**Phase four: the reprocessing.** The heart of the procedure. The young person holds the image in focus, follows the bilateral stimulation, and reports whatever comes. The clinician monitors the SUD and the body sensations, and adjusts the stimulation and the pacing, and periodically asks the young person what they are noticing.

**Phase five: the installation.** The new associations — the new images, the new beliefs, the new body sensations, the new links to the past and to the present — are explicitly installed, one at a time, with the bilateral stimulation. This phase is commonly the most useful and the most neglected, and a student should know that a practitioner who stops at the end of the reprocessing has delivered an incomplete treatment.

**Phase six: the body scan.** A bilateral stimulation period in which the young person attends to the body and reports any remaining sensations. The purpose is to complete the processing of the autonomic component.

**Phase seven: the completion.** A final bilateral stimulation period, and the young person is asked what they would like to address, and any remaining material is addressed briefly.

**Phase eight: the review.** The re-measurement of the SUD, the body sensations, and the vividness, and the review of the progress across the whole treatment.

## 3.2 The SUD and the other measures

The **subjective units of disturbance** are the young person's own rating of the distress associated with the memory, on a scale of zero to ten, or on the widely used pictorial scale, and they are the primary outcome measure within the protocol and the most important thing to chart.

The **body sensations** are the physical sensations associated with the memory, and the **vividness** is the rating of how vivid the image is. These three measures are recorded at the assessment, at the end of each reprocessing set, and at the completion, and the chart is a clinical document and should be part of the case record.

## 3.3 The bilateral stimulation methods

The methods are of three kinds, and the choice among them is made on the basis of the young person's preference, their comfort, and the evidence.

**Horizontal eye movements**, the original method, with the tracking of the therapist's hand moving from side to side.

**Bilateral auditory stimulation**, with alternating tones delivered through headphones, one ear at a time, so that the sound alternates from left to right.

**Bilateral tactile stimulation**, with the hands, or with the feet, or with the shoulders, tapped alternately.

**The butterfly variant**, in which the young person taps their own thighs alternately while tracking the therapist's moving hand with their eyes, and which is used with young children.

The most common finding in the comparative studies is that all of the effective methods work and that the choice is best made collaboratively.

# 4. The Mechanisms

## 4.1 The competing accounts

Three families of explanation have been proposed, and a student should be able to state them and the evidence for each.

**The ocular motor account.** The eye movements produce a specific effect on the autonomic nervous system, and in particular a reduction in the sympathetic arousal. The evidence for a specific autonomic effect of horizontal eye movements is weak and the findings are inconsistent, and the account does not explain why the auditory and the tactile methods work as well as they do.

**The attentional and the associational account.** The bilateral stimulation occupies the attention in a way that permits the free associative flow that the reprocessing requires, and that reduces the "avoidance" of the memory that characterises the unprocessed form. This is the account with the best support, and the support comes from the studies that found the effect with several stimulation methods and that found a reduced effect when the bilateral stimulation was replaced by a non-bilateral control.

**The "novelty" and the working-memory account.** The bilateral stimulation occupies a part of the working memory that is otherwise occupied by the avoidance of the memory, and the consequence is a displacement of the memory into a different representational system. This account has a plausible neurocognitive profile and some supportive findings, and it remains contested.

## 4.2 The consensus position

The field's current position is that the mechanism is not known, that the bilateral stimulation is a **provocative technique** rather than a treatment in its own right, and that the therapeutic work is the associative processing that the stimulation makes possible.

This position has an important clinical implication: **the practitioner is not required to believe the mechanism in order to deliver the treatment competently**, and a practitioner who is uncomfortable with the bilateral stimulation can deliver the same treatment with a different attention-holding method, and the protocol's clinical structure is what does the work.

# 5. The Paediatric Adaptations

### 5.1 The differences from the adult protocol

The paediatric protocol is a genuinely different protocol and a practitioner should know the differences.

**The assessment is longer and more play-based.** A young person of seven cannot give a detailed trauma narrative, and the clinician gathers the history through play, through the parent's account, through the drawings, and through the young person's own account in whatever form the young person can manage.

**The preparation is longer and more active.** The clinician teaches the technique explicitly, and the young person practises it, and the young person chooses the method, and the young person is taught the "safe place" and the "happy place" and the "calm place" in detail, and these are used throughout the procedure as the internal anchor.

**The parent is in the room.** The presence of a safe caregiver is the single most important element in the paediatric protocol, and the clinician actively coaches the parent during the procedure, and the parent's role is to be a secure base, to model calm, and to be available for comfort.

**The body work comes first.** The clinician spends a substantial amount of time in the preparation phase on the body's signals and on the young person's capacity to notice them, because the somatic component of the trauma memory is the last to change and the first to be triggered.

**The number of sets is small and the pace is slow.** A young person processes for a few minutes and then stops, and the sets are short, and the young person is given control over the stopping.

**The language is concrete and the images are drawn.** The young person's own drawings of the memory and of the safe place are used, and the drawings are worked with.

**The reprocessing is more affectively intense and the clinician intervenes more.** The clinician's "resourcing" interventions, in which the young person is taken back to the safe place and to the positive resource, are used frequently, and the protocol's guidance is that the clinician should not let the young person's distress exceed a certain level.

### 5.2 The evidence

The evidence for the paediatric EMDR protocol is good, and the studies are generally randomised controlled trials with standardised outcome measures, and the results are consistently positive, with large effect sizes.

The evidence is best for the **single-incident traumatic events** in childhood: the accidents, the disasters, the school shootings, the medicalprocedures, and the sexual abuse where the event is discrete. The evidence for the **developmental trauma** is much weaker, and the reason is methodological: the developmental trauma is not a discrete memory, the standard SUD measure does not apply well, and the protocol's structure assumes a specific and bounded target.

The comparative evidence shows the paediatric EMDR to be **comparable to the trauma-focused cognitive behavioural therapy** on outcome measures, and in some studies superior, and a recent network meta-analysis of the paediatric trauma treatments placed it among the first-line recommendations.

# 7. EMDR with Children and Adolescents

## 7.1 The developmental modifications in practice

The following are the modifications that a practitioner working with adolescents should know, and they are more specific than the general list in Section 5.

**The parent is the co-therapist.** The parent is in the room, and the parent's job is to be a secure base: to sit quietly, to be emotionally available, to model calm, to not ask questions about the memory, and to hold the young person's hand if the young person wants that. The clinician coaches the parent before the session and gives the parent a specific role, and the parent who has not been coached will talk, and the talking will derail the procedure.

**The safe place is a concrete sensory place, not a fantasy.** A fifteen-year-old's "safe place" is a specific and sensory description: the beach at a particular time, a specific room, a specific piece of music. The clinician elicits it in detail and the young person draws it, and the drawing is used as the anchor throughout the session.

**The "external focus of attention" is taught as a body sensation.** The young person is taught to locate a physical sensation in the body — a point on the sternum, the top of the head, the hands — and to attend to it, and the sensation is the anchor when the memory's affect rises. With young people this works better than the cognitive "external focus" that the adult protocol specifies, and the paediatric protocol says as much.

**The clinician intervenes more often.** The adult protocol is relatively permissive about the young person's distress during the reprocessing. The paediatric protocol is not: the clinician monitors the affect continuously and intervenes with a resourcing intervention when the young person's affect exceeds a manageable level, and the interventions are frequent.

**The sets are short and the young person controls the stopping.** A set is a few minutes rather than a full "round", and the young person is told explicitly at the start that they can stop at any time and that stopping is not a failure.

**The installation is done with the young person's own words.** The new associations that emerge during the reprocessing are written down, in the young person's words, and the installation goes through them one at a time, and the young person approves each one.

## 7.2 The specific applications with young people

**Single-incident accidents.** The best-evidenced application in the paediatric population, and the protocol maps almost perfectly onto the presentation, and the young person is usually stabilised and in a school and can be treated in a small number of sessions.

**School and community trauma.** The evidence from the school-based and the community-based programmes is good, and the group delivery of the first-aid version of the protocol has a substantial evidence base.

**Medical procedures.** The protocol was developed partly for young people undergoing painful procedures, and the modification for this application is the "prescripted image" technique, in which the young person is given a prepared image to hold while the painful stimulus is applied, and the practice is now well established in paediatric pain services.

**Sexual abuse.** The evidence is good for the protocol with a discrete abuse event, and the evidence is much weaker for the developmental pattern, and the practitioner must be careful about the demands the protocol makes on a young person who is still in the situation.

**Grief.** The protocol has a well-established application to the traumatic grief of sudden loss, and the paediatric grief application is described in the literature.

**Specific phobias and the anxiety disorders.** The protocol is effective, and in this population the question of whether a trauma-focused protocol is indicated at all, as opposed to the graded exposure of Chapter 25, is a live one.

## 7.3 The limits with young people

**The developmental trauma presentation is a poor fit.** The standard target of the protocol — a discrete, bounded, sensory memory — is not available in the developmental presentation, and the clinician who applies the protocol to a young person with a chronic relational trauma will either find that there is no target or will find that the target is a composite that the young person cannot hold.

**The protocol requires a capacity to stay with an affect.** A young person who dissociates in session cannot do the reprocessing, and the clinician should be prepared for the possibility that the dissociative response is a poor sign for the suitability of the protocol and not only a technical difficulty.

**The protocol's structure can pressure the young person.** The eight-phase structure, the SUD rating, the repeated questions about the memory — a young person who has been assessed repeatedly and who is being

asked to rate their distress on a scale can experience the procedure as another demand to perform.

**The parent in the room is a double-edged intervention.** The parent is the secure base, and the parent is also the person who may have been the source of the trauma, and the protocol requires the clinician to have established which before the session, and the clinical judgement required is significant.

## 8. Case Illustration: The Boy Who Kept Checking the Rear Window

**Presentation.** Ruben is twelve. Four months ago he was in a car that was hit by a van, and his mother was in the back seat with him. His mother was seriously injured and Ruben was not, physically. Since the accident, Ruben will not sit in the back of any car, he checks the rear window constantly, he has not slept in his own bed, he wets the bed twice a week, and his school attendance has dropped by half. The referral is from the paediatrician, who is asking for trauma-focused treatment.

**The history and the stabilisation.** The practitioner conducts the full history. The important findings are: no previous mental health history; no current risk; a stable and safe home; the mother is recovering well and is clinically stable; and the family are cooperative. The practitioner also takes the school and the paediatrician's details, and establishes that there is no ongoing threat.

The practitioner also establishes what the mother knows and does not know, and notes that Ruben's father, who separated from the mother before the accident and who is estranged, has not been informed. The practitioner discusses this with the mother and with the school and makes a safeguarding assessment, and the finding is that the risk to Ruben from his father is low and the question is whether informing him is in Ruben's interests, and the practitioner takes Ruben's view on this in the second session and records it.

**The preparation.** Over three sessions, the preparation is done. Ruben chooses the butterfly method, which he says he can do "without anyone noticing", and this is a good choice because it is discreet and because it gives him control. The safe place is established in detail: his grandfather's boat shed at the coast, the smell of the oil, the sound of the water, the blue chair. He draws it. The external focus is located: he and the practitioner find a point on his sternum that he can attend to, and the practitioner teaches him to move his attention there when the distress rises, and the teaching is repeated in each session.

The body work is done in the preparation phase, and it is given substantial time, because the practitioner has noticed that Ruben's first sign of distress is a change in his breathing, and the practitioner wants him to be able to notice it before the distress is visible.

The mother is coached: she sits on the boy's left, she does not speak during the processing, she breathes normally, she does not ask him what he is thinking, and if he reaches for her hand she holds it and says nothing.

**The assessment.** The chosen target is the moment of the impact, and Ruben describes it: the van came from the side, the noise, his mother's voice, and the moment after. The SUD is nine. The body sensations are in his jaw and his chest. The image is vivid. The practitioner charts all three and notes that the chart is going to be the main clinical document in this treatment.

**The reprocessing.** There are three sets over two sessions.

In the first set, the boy reports the image, the noise, his mother's voice, and then reports that the van "didn't even slow down" and that this is new information — that he had not remembered the detail that the van did

not slow down, and that it had been going fast, and that it had been going fast because of the roadworks, and that the roadworks are always there, and the practitioner notes that this is the associative processing, that the memory is being linked to the ordinary world of the road and the roadworks and the ordinary traffic.

In the second set, the boy reports the moment after the impact, and this is where the affect rises sharply, and the boy's breathing changes, and the practitioner intervenes with a resourcing intervention and takes him to the boat shed, and the boy's breathing settles, and the practitioner says: "You can come back to it, or we can stop here today." The boy says: "I want to come back."

In the third set, the boy reports something that surprises the practitioner: "I keep looking at the back window because I keep thinking Mum's going to say she's hurt again." The practitioner says nothing and lets him continue, and the boy goes on: "She's not, is she. She's at home. She's walking. I saw her walking yesterday and I didn't even see the bandage." And then he says: "I think I keep looking in case she needs me to look after her."

The practitioner recognises this as the essential material, and it is the material that the reprocessing exists to reach: the boy's checking is not a fear of a repeated accident; it is a ten-year-old's vigilance about his mother's care, and the accident has given him a reason to perform it.

**The installation.** The new associations are installed one at a time, with the bilateral stimulation. The practitioner asks the boy what he would like to remember about the accident, and the boy says: "That I looked after her, and that she was all right, and that I can stop." The practitioner installs this. The body scan is done, and the boy's remaining sensation is in his jaw, and the body scan reduces it, and the boy reports that it is "like a tooth that isn't there any more".

**The completion and the review.** The SUD is two. The body sensations are zero. The vividness is three. The boy says: "It was a bad accident. It just isn't happening now."

**The follow-up.** The practitioner asks what the boy thinks will be different at home. He says: "I think I'll sleep in my bed." The practitioner does not tell him that he will; she asks him what he would need to do, and he says: "Nothing. I think I'll just do it." The practitioner says: "Let's see."

**The outcome.** At the one-month review the boy is sleeping in his bed, has no bedwetting, has returned to school, and has not checked the rear window in the car in the last two weeks. The mother reports that he has asked to sit in the back again, and that he has chosen the music. The practitioner is clear that this is a good outcome and is equally clear that the work was the work of the reprocessing and the installation and not the reassurance.

**The interpretation.** The case illustrates the protocol and its specific pedagogic point: the target memory was the accident, and the material that mattered was the meaning attached to it, and that meaning — that the checking was a way of looking after his mother — was only accessible through the associative processing and not through the history, and would not have been reached by any of the cognitive procedures in Chapter 16. It also illustrates the paediatric discipline: the parent in the room and coached, the short sets, the resourcing intervention and the offer to stop, the chart as the document, and the installation as the phase that makes the change durable.

# 9. Evidence and Research Support

## 9.1 The status of the evidence

**The efficacy of EMDR is well established.** The method has been subject to more controlled trials than almost any other psychological treatment, and the meta-analyses report large and consistent effects for the PTSD and the phobias in adults. It is recommended as a first-line treatment in the major international guidelines.

**The paediatric evidence is good and growing.** The randomised controlled trials with children and adolescents show substantial effects on symptom measures and on the measures of functional impairment, and the effect sizes are large.

**The comparison with the trauma-focused cognitive behavioural therapy is favourable.** The network meta-analyses of the paediatric trauma treatments have placed EMDR among the first-line recommendations, generally comparable with or slightly ahead of the trauma-focused cognitive behavioural therapy, and ahead of the treatments that are not trauma-focused.

**The evidence on the mechanisms is genuinely inconclusive**, and the field's position is that the mechanism remains unknown and that the stimulation functions as a device for the associative processing. The studies that found effects with several stimulation methods, and with a non-bilateral control in some conditions, are the most informative.

**The evidence for the developmental trauma application is weak**, and the reasons are methodological and are described in Section 7.3.

### 9.2 Limitations of the evidence

**The samples are dominated by adults with single-incident trauma**, and the generalisation to children with developmental trauma is not supported.

**The measurement of the outcome within the protocol is subjective** and the SUD is a single-item measure that is vulnerable to expectancy effects, and the between-session measures are the ones on which the claims of the method have to stand.

**The fidelity measurement has been difficult**, and the protocol's eight phases and its specific instructions are detailed enough that delivery varies.

**The trials are frequently conducted by EMDR researchers**, and the allegiance effects have been examined in this literature and are substantial, and the field has itself commissioned critical reviews.

**The long-term follow-up is limited**, and the question of what happens to the young person in the years after the treatment, and whether the memory returns in a form, is under-researched.

**The comparison with the alternative trauma-focused treatments is relatively recent**, and it will take more and larger trials to establish the comparative position with confidence.

## 10. Strengths and Limitations of EMDR

### 10.1 Strengths

**It is brief.** A young person with a single-incident trauma may be treated in a small number of sessions, and brevity is a genuine clinical advantage.

**It is a first-line recommended treatment**, and the practitioner will be able to access it in the referral pathways of the major systems.

**The treatment does not require the young person to narrate the memory in detail**, which is one of its most important practical advantages in the paediatric population and one of the reasons it is well suited to young people who cannot or will not tell the story.

**It targets the autonomic component**, and the body work is integrated into the protocol rather than added to it.

**The installation phase is a specific and valuable technique** that is often omitted and that is one of the more transferable elements in the book.

**The chart is a good clinical document** and it makes the progress of the treatment visible to the young person, to the parents, and to the referrer.

### 10.2 Limitations

**The mechanism is unknown**, and a practitioner should be honest with a referring agent about this, while also being able to point to the efficacy evidence.

**The protocol's structure can pressure the young person**, and the repeated ratings and the structured questions are a poor fit with some young people.

**The developmental trauma is a poor fit**, and the protocol should not be applied to it by analogy.

**The training and the certification requirements are significant**, and the protocol should not be delivered by an untrained practitioner.

**The parent-in-the-room requirement is a genuine constraint**, and in some cases there is no safe parent, and the protocol's paediatric form then cannot be used in its standard form.

## 11. Cultural and Ethical Considerations

### 11.1 Culture, memory, and the treatment of the memory

**The meaning of a memory is culturally constituted.** The same event means different things in different contexts, and the processing of a memory is a process of linking it to a frame, and the frame the practitioner offers is culturally specific. A practitioner who assumes a universal phenomenology of traumatic memory will misdescribe the experience of some young people.

**Some events are not traumatic for the young person who experienced them**, and the decision to treat a memory as traumatic should be made on the basis of the young person's own account of it rather than on the basis of the event type. A young person who was in the accident and who says she was fine may be minimising, or may be telling the truth, and the assessment should be able to tell the difference.

**The cultural resources for processing a trauma are frequently available and are frequently ignored.** Many communities have established practices for the marking of loss and for the processing of frightening events, and the individual protocol can be respectful of these or can displace them, and the practitioner should ask.

**The language of the procedure is specific.** The protocol is translated into a great many languages, and the translation of the SUD scale, of the "safe place", and of the instructions for the bilateral stimulation is not a simple matter, and a practitioner working across languages should check the validated version.

### 11.2 Ethical considerations

**Informed consent with a developmental understanding.** The young person must consent in a form appropriate to their development, and the parent's consent and the young person's assent are both required, and the young person's ongoing consent during the procedure is monitored.

**The right to stop.** The young person must be told, at the start and repeatedly, that they can stop, and the protocol's design must make stopping easy and must not make it a failure.

**The prohibition of the compulsory retrieval of a memory.** The procedure works with the memories that the young person brings, and a practitioner who pressures a young person to retrieve a specific memory has departed from the protocol and has introduced a significant risk.

**The boundaries of the memory work.** The protocol is for the processing of a specific memory, and it is not an invitation to explore the whole history, and the practitioner who uses the reprocessing as a route into general history has left the evidence base.

**The confidentiality of the memory.** The young person must know, before the session, who will hear what is said, and the chart and the recording of the SUD are records of a young person's distress and are sensitive documents.

**The relationship to the safeguarding framework.** The disclosure of abuse within the protocol is a disclosure to a third party, and the practitioner must know the local reporting obligations, and must handle the situation with a specific plan agreed in advance.

**The prohibition on the use of the procedure with the child in a state of acute crisis.** The history and the stabilisation phases of Chapter 38 are the prerequisites, and a practitioner who proceeds to the reprocessing with an unstabled young person is doing harm.

## 12. Key Terms

**Key Terms at a Glance**

- **Eye movement desensitisation (EMD)** — The original name of Shapiro's procedure, in which a distressing memory was held in focus while the eyes moved horizontally.
- **EMDR** — Eye movement desensitisation and processing, the current name of the eight-phase protocol.
- **Adaptive information processing model** — The model in which the pathology lies in the failure to complete the processing of a memory, and the treatment in the completion of that processing.
- **Unprocessed memory** — A memory stored in a form that remains vivid, is experienced in the present tense, retains the original autonomic response, and is disconnected from the rest of the autobiographical narrative.
- **The link** — The missing connection between the unprocessed memory and the general network of autobiographical knowledge, and the element whose restoration the treatment produces.
- **Provocative technique** — The contemporary understanding of the bilateral stimulation, as a device for eliciting and sustaining the associative processing rather than as a treatment in its own right.
- **The eight phases** — History and stabilisation, preparation, assessment, reprocessing, installation, body scan, completion, and review.
- **Subjective units of disturbance (SUD)** — The young person's own rating of the distress associated with the memory, and the primary outcome measure within the protocol.
- **Body sensations** — The physical sensations associated with the memory, charted alongside the SUD and the vividness.
- **Vividness** — The rating of how vivid the image of the memory is.
- **The chart** — The clinical document recording the SUD, the body sensations, and the vividness across the phases and the sessions.
- **Bilateral stimulation** — The horizontal eye movements, the alternating auditory tones, the alternating tactile taps, and the butterfly variant.
- **The butterfly method** — The variant in which the young person taps their own thighs alternately while tracking the moving hand, used with young children and with those who need discretion.
- **Installation** — The phase in which the new associations are explicitly established, one at a time, with the bilateral stimulation; frequently the most neglected phase.
- **Body scan** — The bilateral stimulation period in which the young person attends to the body and reports any remaining sensations, completing the autonomic component.

**Key Terms at a Glance (continued)**

- **The internal and the external focus of attention** — The cognitive anchors used during the procedure, which in the paediatric protocol are taught as a body sensation.
- **The safe place** — A concrete, sensory, personally meaningful resource, elicited in detail and used as the anchor throughout the session.
- **Resourcing intervention** — The clinician's intervention that takes the young person back to the safe place and the positive resource when the affect exceeds a manageable level.
- **The set** — A short period of reprocessing, in the paediatric protocol lasting a few minutes, with the young person controlling the stopping.
- **The parent as co-therapist** — The coached role of the safe caregiver in the paediatric protocol: to sit quietly, to model calm, to be available, and not to ask questions.
- **Prescripted image** — The technique in which a prepared image is held during a painful procedure, developed from the EMDR principles in paediatric pain services.
- **The developmental trauma mismatch** — The problem of applying a protocol designed for a discrete, bounded memory to a young person whose trauma is a chronic relational pattern.
- **The single-event and the developmental distinction** — The distinction on which the strength of the paediatric evidence depends.
- **The biographical gap** — The separation of the young person from the event that is the target of the reprocessing, in which the affective component remains unprocessed while the cognitive component is accessible.

## 13. Review and Discussion Questions

**Review and Discussion Questions**

1. Describe the origin of the EMD procedure and the observation on which it was based.
2. Explain the controversy over the procedure and how the field resolved it.
3. State the three findings that the well-controlled studies established.
4. Explain the shift from the eye movement desensitisation to EMDR and its clinical significance.
5. State the central claim of the adaptive information processing model.
6. Explain the components of the model: the unprocessed memory, the dysfunction, the link, and the bilateral stimulation.
7. State the eight phases of the protocol and the purpose of each.
8. Explain the SUD, the body sensations, and the vividness, and the role of the chart.
9. Describe the four bilateral stimulation methods and the finding about their equivalence.
10. State the three competing accounts of the mechanism and the evidence for each.
11. State the field's consensus position on the mechanism and its clinical implication.
12. State the eight differences between the paediatric and the adult protocol.
13. Summarise the evidence for the paediatric protocol and state the two groups for which it is strong and weak.
14. State the seven specific adaptations for adolescents.
15. Explain the double-edged nature of the parent-in-the-room requirement.
16. State the four limits of the protocol with young people.
17. Describe the case of Ruben and state the two features of it that generalise.
18. Summarise the status of the evidence and its six limitations.
19. State the six strengths and the six limitations of the procedure.
20. Explain the four cultural considerations for EMDR practice.
21. State the seven ethical requirements for the procedure.

## 14. Practice Activities

**Practice and Application**

### Activity 39.1 — The Four Phases Audit (75 minutes, individual)

Take a young person from placement with a history of a frightening or frightening-adjacent event and write the eight phases as they would apply, with a specific plan for each. Then write the specific criterion you would use to decide whether to proceed to the reprocessing at all. Then write what you would do if, at the end of the preparation, you concluded that the young person was not stabilised enough. The third step is the one that the chapter is really about, and most students find it difficult to write.

### Activity 39.2 — The Installation Exercise (60 minutes, individual)

Take a case and write the installation as it would actually be spoken, in the young person's own words, with each new association given separately and with the bilateral stimulation noted between each. Then write the version that omits the installation, and compare. The comparison is usually striking, and it is the clearest demonstration in the book of why a specific technical detail matters.

### Activity 39.3 — The Mechanism Discussion (60 minutes, small group)

In groups of four, take the question "why does this work?" and produce four different answers: the ocular motor account, the attentional and associational account, the working memory account, and the "we do not know" answer. Then write the clinical decision that each answer would lead to. The last step is the important one, because it is the argument for why a practitioner can deliver the treatment competently without settling the mechanism, and the groups usually find that the clinical decisions are the same.

### Activity 39.4 — The Paediatric Suitability Screen (60 minutes, individual)

Write a suitability screen for the paediatric EMDR protocol, with a criterion for each of: the presence of a discrete, bounded target memory; the stability of the young person; the safety of the caregiver; the capacity to stay with the affect; the capacity to report the SUD; and the absence of ongoing threat. Then apply the screen to two cases from placement, one of which will fail it. The exercise teaches the selection decision, which is the decision with the largest clinical consequences in the whole protocol.

## 15. Annotated Reading Pathways

**For the protocol.** Read Shapiro (2017) for the contemporary text, and read the EMDR International Association's practice guidelines and the child and adolescent protocol. The guidelines are the clinical standard and they are short.

**For the model.** Read Brown (2013) and Shapiro and Luycky (2016) for the adaptive information processing model and the mechanism review.

**For the paediatric evidence.** Read the paediatric systematic reviews and the network meta-analysis of the paediatric trauma treatments, and read Bergmann's critical reviews. The critical reviews are essential and they are of a high quality.

**For the mechanism.** Read the comparative studies of the stimulation methods, which are the most interesting empirical literature in the field, and Stickgold's neurocognitive account.

**For the practice.** Read the paediatric protocol, and read the case literature on the use of EMDR in schools, in community settings, and in paediatric pain services, which are the applications most likely to be relevant to a practitioner in this programme.

# Practice Laboratory and Extended Worked Example

This laboratory turns **EMDR and Bilateral Stimulation** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is shapiro's protocol, the adaptive information processing model, and careful adaptation for children. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is safety, regulation, emotion, memory, relationships, and paced therapeutic work. The mechanism to keep in view is how threat, arousal, avoidance, meaning, and relational safety shape what a young person can feel, remember, and learn. The characteristic professional risk is moving into traumatic material before stabilisation, confusing calm with shutdown, or making disclosure the price of care. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

## A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in stabilisation sessions, trauma-informed schools and services, caregiver work, and specialist treatment pathways, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and**

**eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Priya is fifteen and is seen in a school counselling service for shame after academic failure. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Priya's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Priya explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on safety, regulation, emotion, memory, relationships, and paced therapeutic work. The first intervention is deliberately modest. Priya chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Priya has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Priya can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for EMDR and Bilateral Stimulation

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **EMDR and Bilateral Stimulation** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

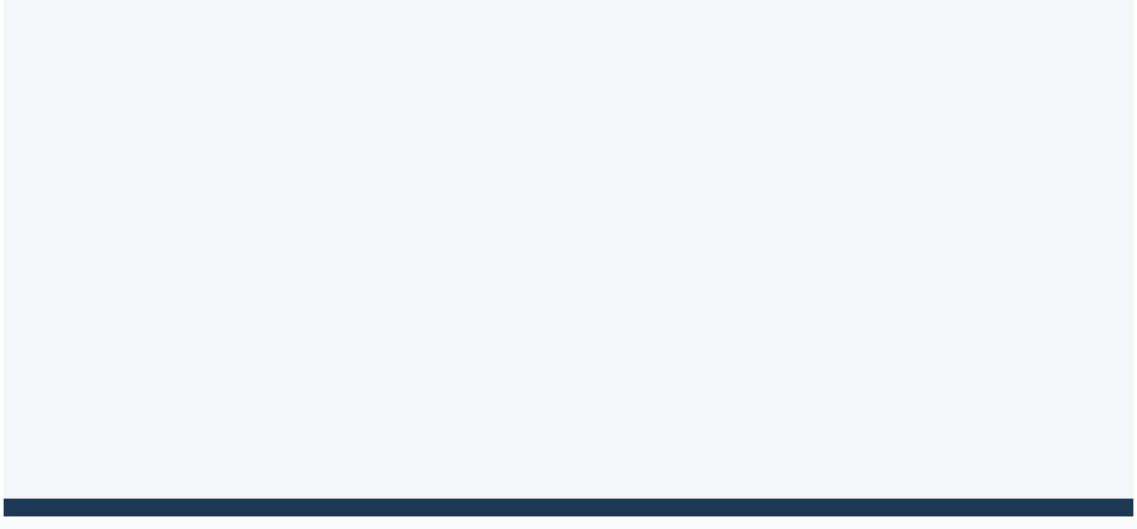
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **EMDR and Bilateral Stimulation** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **EMDR and Bilateral Stimulation**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.



**Written consolidation.** In 250 words, explain EMDR and Bilateral Stimulation to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the

listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 40

# Stabilisation, Grounding, and Phase-Oriented Work

Skills for the first phase of trauma treatment and the maintenance of stability between sessions.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain what stabilisation is for, and distinguish it from both the processing work and the ordinary supportive conversation.
- State the core skills of a stabilisation programme and describe how each is taught to a young person.
- Describe the grounding techniques and the conditions under which each is used.
- Explain the phase-oriented approach to case management, and the criteria that determine the phase.
- Apply a stabilisation programme to a case involving a young person with severe dysregulation.
- Critically evaluate the limitations of the stabilisation work, including the risk that it becomes a way of avoiding the difficult work.

## Chapter Overview

Stabilisation is the least glamorous and the most necessary work in this book. It is the work that happens before anything else can happen: the young person who cannot remain in the room, who cannot stop checking the door, who cannot sleep, who cannot stop dissociating in the middle of a conversation, cannot do a cognitive technique, cannot process a memory, and cannot be helped by a practitioner who is trying to do either.

The central clinical proposition of this chapter is simple: **a young person's capacity to be in a relationship, to think, and to feel is a capacity that is regulated by the body, and the body can be taught to be more regulated.** A young person who is constantly in a threat state is not being difficult; the nervous system is doing what it was trained to do, and it can be trained differently, and the training takes time and repetition and it usually happens before any talk about the trauma.

The skills themselves are deceptively simple, and the chapter is largely devoted to them: the orienting to the environment, the grounding through the senses, the paced breathing, the "safe place", the "container", the "light switch", the body scan, the grounding through movement, the time travel to a safe memory, and the interpersonal skills of asking for help and of saying no. Each of them is a well-specified technique with a specific mechanism, a specific teaching procedure, and a specific set of contraindications, and a practitioner who knows them can do a great deal with a young person in the first weeks of a treatment.

The chapter also treats the two most common failures of this work: the practitioner who stabilises the young person in order to be able to do the processing work, and the practitioner who stabilises the young person instead of doing the processing work. The second is more common and is more insidious, and the chapter sets out the clinical criteria that distinguish them.

## 1. What Stabilisation Is For

### 1.1 The purpose

Stabilisation has four purposes, and a student should be able to state all four.

**To widen the window of tolerance.** A young person who is constantly hyperaroused or constantly shut down cannot process information, and the widening of the window is a precondition for everything else.

**To build the capacity to remain present.** Dissociation, avoidance, and the dorsal vagal shutdown are the young person's solutions to an intolerable state, and the solutions have to be replaced with something less costly before the original state can be addressed.

**To establish the working relationship.** A young person with a developmental trauma history will not be able to trust a practitioner until the practitioner has demonstrated that they can be relied upon to be present, to be predictable, and to be controllable — and the only demonstration that works is the demonstrated over time.

**To restore the young person's ordinary functioning.** School attendance, sleep, eating, and the relationships are the things that are immediately at stake, and the restoration of them is a legitimate goal in its own right and is frequently the thing the young person most wants.

## 1.2 What stabilisation is not

**It is not the trauma processing.** A young person can be perfectly stabilised and still have not begun to process anything, and the work must not be confused with the work.

**It is not supportive counselling.** The supportive conversation is unstructured, is about reassurance, and is of undetermined duration, and it does not build the specific capacities that the processing work requires. It is valuable and it is not the same thing.

**It is not symptom suppression.** The aim is not to make the symptoms go away; the aim is to give the young person a set of skills that they can use when the symptoms arise, so that the symptoms are no longer the only option.

**It is not a prelude that can be skipped.** A practitioner who intends to do a trauma-focused intervention and does not stabilise first will produce a worse outcome than a practitioner who never intended to do one.

## 1.3 The evidence for the stabilisation work

The evidence base here is more limited than the evidence base for the specific trauma-focused protocols, and a student should be able to describe it accurately.

**There is good evidence for the general principle** that the reduction of arousal precedes the cognitive work, that the reduction is achieved through the body, and that a young person who is dysregulated cannot use the cognitive and the narrative techniques. This principle is well supported across the psychophysiology and the clinical literature.

**The evidence for the specific individual skills is thinner and more recent.** The systematic reviews of the grounding, the stabilisation, and the self-regulation skills in the treatment of trauma report positive effects on the symptom measures and on the distress, with the most consistent findings for the paced breathing, the grounding through the senses, and the orienting.

**The evidence for the phase-oriented model as a package is thin**, and the most useful empirical support for it is indirect: the trials of the specific trauma-focused protocols with children, in which the protocols that include a substantial preparation phase do at least as well as those that do not, and the trials of the treatments that are *only* stabilisation, which show meaningful improvements in functioning and in the symptoms without any processing.

**The clinical consensus is strong** even where the evidence is thin, and this is one of the cases in the field in which the clinical consensus is better established than the empirical support, and a student should be able to

say so.

# 2. The Core Skills

## 2.1 The orienting skill

**Orient to the here and now.** The young person is asked to name, in order, five things they can see, four they can hear, three they can touch, two they can smell, and one they can taste. The technique is derived from the standard grounding exercises and it is one of the most useful in the repertoire, because it requires no training, it produces a measurable change in the autonomic state within ninety seconds, and it is available to the young person at any moment.

**Orient to the internal.** The young person is asked to name five things they can feel within their body. This is harder, it is more useful for the young person who is dissociating, and it is the bridge to the body scan.

**Orient to the temporal.** The young person is asked, in the middle of distress, to name the day, the date, the time, the season, the weather, and their age. This is a simple and effective technique for a young person who has lost track of where they are, and it is particularly useful with a young person who is dissociating or who is having a flashback.

**The teaching.** The technique is taught in a low-arousal moment, it is practised in a low-arousal moment, it is written on a card, and the young person is taught to use it proactively as well as reactively. The proactive use — using the card when the arousal is at a four rather than a nine — is the difference between a skill that is used and a skill that is not.

## 2.2 The grounding through the senses

**The five senses as an anchor.** "Feel the chair. Feel the floor under your feet. Hear the hum of the light. See one green thing. Feel the temperature of the air on the back of your hand." The technique is taught as a script and it is the most portable of the skills, because it requires nothing and it can be used in a corridor, on a bus, in a waiting room.

**The technique is for the young person who is in the room with the practitioner**, and the practitioner should use it themselves in the room, and the practitioner should say, out loud, when they are using it, because the demonstration is part of the teaching.

**The contraindication.** For a young person whose abuse involved sensory detail, the sensory grounding can be activating rather than settling, and the practitioner should ask about this before teaching it, and the alternatives are the movement-based and the orientation-based techniques.

## 2.3 The paced breathing

**The physiological rationale.** Slow exhalation lengthens the interval between heartbeats, and the vagal tone increases, and the arousal reduces. The mechanism is straightforward and it is one of the few places in this book where a specific physiological claim can be made and used with confidence.

**The technique.** The young person is taught to breathe in for a count of four and out for a count of six, or to use any other ratio in which the exhalation is longer than the inhalation. The practitioner should not over-specify: the ratio matters less than the exhalation being longer, and a young person who finds counting irritating should be given a simpler version.

**The teaching.** The technique is best taught lying down, in a low-arousal moment, with the practitioner doing it alongside the young person, and the young person is taught to notice the difference between the breathing before and after.

**The caution.** The breathing must not be used with a young person who is in the dorsal vagal state, because the deepening of the exhalation will deepen the shutdown. The breathing is for the sympathetic state; the dorsal vagal state requires orienting and movement.

## 2.4 The safe place and the container

**The safe place** is a concrete, sensory, personally meaningful location, and it is taught in detail. For a young person who finds it hard to imagine, a photograph, a place in the building, or a physical object can serve. The safe place is used as the resourcing intervention during the processing work, and it is used in the stabilisation work as a general resource.

**The container** is a different and complementary technique. The young person is asked to imagine a container — a box, a safe, a vault, a large drum — that can hold whatever they need to put away. The contents are named: the frightening images, the bad thoughts, the difficult feelings, the things that are too much. The young person then imagines placing them in the container and closing the lid. The technique is cognitively simple and it is used with young people who are ruminating or who are overwhelmed by intrusive material, and it is best taught in the drawing, with a box drawn and the contents drawn in it.

## 2.5 The body scan

**The technique.** Attention is moved through the body, from the feet to the head, with the young person reporting anything that is noticed, and nothing is interpreted. The practice is derived from the mindfulness-based body scan of Chapter 22, and the developmental adaptation for a young person with a trauma history is that the young person is in control of where the attention goes and can stop at any point.

**The two uses.** The body scan is used in the stabilisation work, as a daily practice that builds the young person's awareness of the body's signals, and it is used in the processing work, as the technique for completing the autonomic component of the memory, which is the last part to change.

**The contraindication.** The body scan is contraindicated in a young person with a history of bodily abuse, and the practitioner should ask before teaching it, and the alternative is the movement-based grounding.

## 2.6 Movement and orienting through the body

**The physical discharge.** A young person who is in a constant sympathetic state needs to move, and the movement should be large, undemanding, and not competitive: walking, running on the spot, pushing against a wall, shaking, jumping, climbing. The practitioner should be prepared to do it with the young person, and the room should be one in which this is possible.

**The orienting through movement.** The "up and down" exercise, in which the young person lies on the floor and moves their gaze up and down while a helper moves a red object, is derived from the EMDR literature and is a genuine orienting technique with a good evidence base.

**The slow, deliberate movement.** Tai chi, yoga, and structured dance have all been used in the stabilisation of young people, and the evidence base is growing, and the group format makes them practical.

## 2.7 The time travel to a safe memory

**The technique.** The young person is asked to recall a specific, real, and genuinely pleasant memory from their own life — not a fantasy, not a generic image, but a real occasion with real detail — and to place themselves in it, in the body, and to notice what they can feel now. The technique works because the recollection of a genuinely safe and pleasant experience is itself an orienting and regulating event, and because it accesses the same systems that the traumatic memory has colonised.

**The specific requirements.** The memory must be real, and it must have been checked with the young person — many young people with a difficult history have very few genuinely safe memories, and the practitioner must establish which ones they have before asking for one. The memory must be detailed. And the practice must be short, because the memory fades and the young person must not be left with the fading.

## 2.8 The interpersonal skills

Two skills are taught in the stabilisation phase because they are the skills that will keep the young person safe and are the skills that are most often missing.

**Asking for help.** The young person practises asking for help in a concrete situation, and the practice is repeated, and the response to the request is guaranteed. A young person who has never had a request met will not make one, and the point of the exercise is that the request is met, every time, in the sessions with the practitioner and in the sessions with the parents.

**Saying no.** The young person practises declining, and again the practice is repeated and the outcome is predictable. This is a skill that a young person with a trauma history frequently does not have, and it is a skill that is also a right, and a practitioner who teaches it is teaching a right as well as a skill.

## 2.9 The skill of the window of tolerance

**The traffic light.** The young person learns to rate their own arousal on a three-colour scale, and to know their own early indicators, and to know what they need at each level. At the green level, the young person is in the learning zone. At the amber level, the young person uses the grounding skills. At the red level, the young person goes to the safe place, the container, or the trusted adult, and does not attempt to process anything.

**The value of the traffic light is that it moves the responsibility for the regulation from the practitioner to the young person**, and that is the objective of the whole phase, and the practitioner who is doing the regulating for the young person has not completed the phase even if the symptoms have reduced.

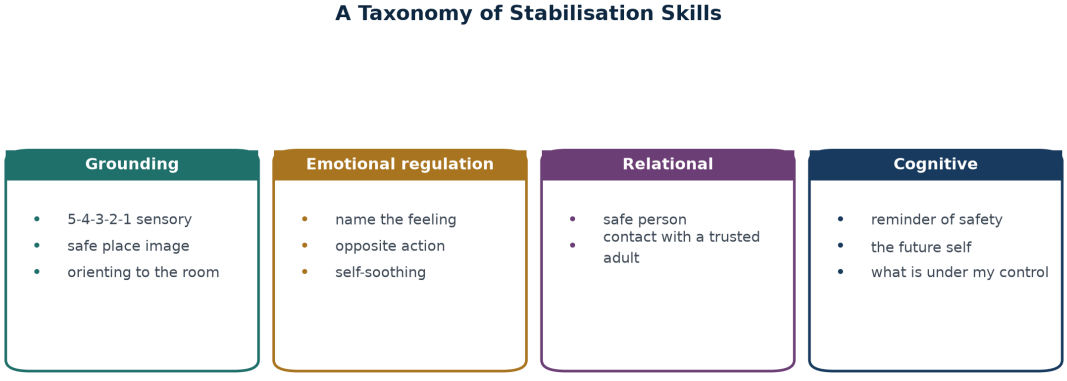


**Figure 40.28** The stabilisation skills arranged as a hierarchy, from the orienting skills through the breathing, the grounding, the body scan, the safe place, the container, and the interpersonal skills, with the traffic-light self-monitoring scheme.

# 4. The Phase-Oriented Approach

## 4.1 The rationale

The phase-oriented approach is the practical response to a problem that is specific to this population. The specific trauma-focused protocols are effective and are the best-evidenced treatments available for the specific phobias and the discrete traumas of childhood, and they are not straightforwardly applicable to the developmental presentation, in which there is no discrete target, the affect is chronic rather than situational, and the young person's symptoms are pervasive rather than circumscribed.

The phase-oriented approach therefore divides the work by the state of the young person rather than by the type of trauma, and it is a management framework rather than a treatment protocol: it determines what kind of work is indicated now, and it specifies the conditions under which a different kind of work becomes indicated.

## 4.2 The phases in practice

**Phase one, the stabilisation and the safety.** The work described in Section 2, and the practical and material work: the housing, the income, the school placement, the legal status, the relationships. The phase continues until the criteria for phase two are met, and the criteria are the ones given in Chapter 38.

**Phase two, the processing.** The specific protocol, and the choice of protocol is determined by the presentation: the trauma-focused cognitive behavioural therapy or the EMDR for a discrete event; the narrative work of Chapter 36 for a young person whose difficulty is organised around a dominant story; the emotion-focused work of Chapter 37 for a young person whose difficulty is organised around an emotion; the attachment-based work of Chapter 34 for a young person whose difficulty is organised around the relationship.

**Phase three, the integration and the rehabilitation.** The rebuilding of the young person's life: the education, the relationships, the futures, the identity. The phase is the most neglected in practice and the most important for the outcome, and the developmental literature is clear that a young person whose trauma has been processed and who has not been helped to build a life is not going to stay well.

## 4.3 The phase transitions as clinical decisions

The phase transitions should be made explicitly and recorded, and the criteria are as given in Chapter 38.

**The transition into phase two is a decision about readiness, and it should be made collaboratively with the young person and, where relevant, with the caregiver.** A young person who does not want to process is not ready, whatever the criteria say, and the work at that point is the work of the phase one, and the practitioner should say so.

**The transition backwards is a decision that requires a formulation.** A young person who deteriorates in phase two is not a failure of the technique; the deterioration is information, and the usual findings are that the young person was not stabilised, or that the caregiver's behaviour has changed, or that a new crisis has occurred, or that the work has gone too fast.

**The transition into phase three is often made too early and is often not made at all**, and the most common reason is that the young person's symptoms have reduced, and the reduction of the symptoms is not the same as the restoration of the life.

### 4.4 The management framework

The phase-oriented approach is usually delivered as a **framework for the whole service** rather than as a treatment for one young person, and in this form it has a number of features that a practitioner should know.

**Phase-specific pathways.** Each phase has its own procedures, its own documentation, and its own review criteria, and the young person's record shows clearly which phase they are in.

**Phase-specific staff.** The practitioners who do the stabilisation work and the practitioners who do the processing work may be different, and this is often a good arrangement, because the demands of the two are different.

**The measurement at each phase.** The measures that are collected at each phase, and the review that compares the phase's outcomes against the criteria for the next.

**The avoidance of the false dichotomy.** The framework avoids the two failure modes: the service that does only stabilisation and never processes, and the service that processes everybody regardless of their readiness.

## 5. Stabilisation with Children and Adolescents

### 5.1 The developmental modifications

**The skills are taught to the young person, not to the practitioner.** A common error in this work is for the practitioner to be the one who does the grounding — and to be the one who does it for the young person, in the session, every time, which means the young person never acquires the skill and the practitioner never becomes unnecessary.

**The skills are taught in the language of the young person's life.** A twelve-year-old's safe place is a specific and sensory place, and a fifteen-year-old's grounding practice may be a song on a playlist, and the practitioner should ask what the young person already does to feel better and build the programme from that.

**The parent is taught the same skills.** The parent's own regulation capacity is the mediator of the young person's regulation, and the parenting work of Chapter 33 and the parental emotion coaching of Chapter 37 are the vehicles. A parent who is dysregulated cannot co-regulate a child, and the practitioner who teaches the young person the skills and does not teach the parent has done half the work.

**The skills are generalised deliberately.** A skill that is used only in the therapy room is not a skill; the practitioner should think in terms of the contexts in which the young person will need them — the corridor, the bus, the playground, the dinner table — and should plan the practice accordingly.

**The developmental order matters.** A young child is taught the sensory grounding and the safe place; an adolescent is taught the traffic light, the interpersonal skills, and the cognitive reframing of the state.

### 5.2 The presentations

**The young person with dissociation.** The dorsal vagal state is the clinical fact, and the intervention is the orienting and the physical, and the movement-based grounding, and the work on the safety, and the practitioner should not attempt to work with the content.

**The young person with hyperarousal.** The sympathetic state, and the intervention is the reduction and the containment, and the work on the sleep, on the caffeine, on the noise, on the schedule, and the physical work.

**The young person with the persistent somatic presentation.** The somatic work of Chapter 43 is the entry point, and the somatic work is frequently the stabilisation work, and a young person who has been told for years that there is nothing wrong with them will be more willing to engage with a somatic intervention than with a psychological one.

**The young person in an unstable placement.** The stability of the placement is the intervention, and the practitioner who is working on the young person's skills while the placement is in flux is working on the wrong level.

### 5.3 The limits

**Stabilisation does not resolve the trauma.** A young person who is perfectly stabilised and whose trauma is unprocessed will remain vulnerable, and a practitioner who is content with the reduction in the symptoms has substituted symptom management for treatment.

**The skills can be used to avoid.** A young person who has learned the grounding thoroughly can use it to avoid the work, and the practitioner who is pleased by the young person's mastery has been outmanoeuvred, and the question to ask is whether the young person is using the skill in the moment of distress or in the moment of the invitation to the difficult work.

**The phase one can become a waiting room.** The practitioner's anxiety about the processing work is the most common reason for the phase one continuing, and the supervisory question — "what would have to be different for us to move to phase two?" — is the most useful.

**The young person who cannot be stabilised.** Some young people cannot be, and the reasons are usually a continued threat, a caregiver who cannot provide safety, or a neurodevelopmental condition that the stabilisation programme has not been adapted for.

## 6. Case Illustration: The Young Woman Who Was Not in the Room

**Presentation.** Nadia is sixteen, and the referral is from a child and adolescent mental health service that has assessed her and diagnosed a complex post-traumatic stress disorder following a year of sexual abuse by a stepfather. The service has referred her for a trauma-focused protocol. The previous two attempts at therapy have ended: one because she did not attend after the first session, and one because the therapist's approach had made her "worse".

**The assessment.** The practitioner meets Nadia for the assessment, and the first thing they do is not to take a history. The first thing they do is to ask Nadia what happened in the previous therapy. Nadia says: "She kept asking me about it. And I'd go somewhere else. And then she'd get more upset than I had, and I'd be the one apologising." The practitioner says: "That's a specific thing. What would you have needed instead?" And Nadia says: "Somebody to ask me what I needed."

**The phase placement.** The practitioner places Nadia in phase one, and the criteria are explicit in the record: no consistent, safe adult in her life; a mother who is not able to be present with Nadia's distress because her own distress is overwhelming her; a persistent somatic presentation with a pain presentation that has not been medically explained; dissociation in the first session; and no capacity to report the SUD on a memory, which is a prerequisite of the protocol she has been referred for.

**The first three sessions.** The practitioner does not ask about the abuse in the first three sessions. The work is as follows.

*Session one.* The practitioner explains the phase model in plain language: "There are two kinds of work here. One is working out what happened and what it did to you. The other is making sure you can survive the ordinary week and sleep and be in a room with people. Most people I've worked with who had a bad experience find the second one first, because the first one needs you to be able to be in a room. So that's what we're doing first." Nadia says: "How long?" and the practitioner says: "I don't know. It depends how fast you get the skills. And we'll be checking." The practitioner then does the orienting exercise with her, in the room, and Nadia notices that she has been looking at the door the entire time, and the practitioner names this and asks about it, and Nadia says: "I'm waiting for him to come in." The practitioner says: "He's not going to come in here. I want to be clear about that. This room is yours for fifty minutes and he is not in it and he is not going to be in it."

*Session two.* The skills. Nadia chooses the grounding that she finds most tolerable, which is not the sensory one — she says the sensory one makes her think of the specifics — and it is the movement-based one and the time travel to a safe memory. Her safe memory is specific: her grandmother's kitchen, the smell of the bread, the sound of the radio. She practises it with the practitioner, and the practitioner practises with her, and Nadia's shoulders come down, and she notices it, and the noticing is the teaching.

*Session three.* The mother. The practitioner sees the mother alone, and the mother's account is that she did not know, that she is "destroyed", that she cannot sleep, that she is frightened of her own daughter because the daughter screams at her, and that she has been told by a service that Nadia "needs to process" and that she has been told by another service that she "needs to be the parent". The practitioner asks the mother the coping question — "How have you been managing?" — and the mother says: "I've been lying on the floor of the bathroom. That's where I go." The practitioner stays with that, and the mother cries, and the practitioner does not move on, and the mother says: "I've been so frightened of her. And she was the one who was hurt."

**The work with the mother.** The practitioner teaches the mother three things, and the first of them is the traffic light, which the mother learns to apply to her own arousal, and which she initially uses to describe Nadia's. The second is the orienting exercise, which the mother practises in the bathroom when she is at the point at which she would usually go and stand outside Nadia's door. The third is the specific change in the relationship: the mother stops going to Nadia's door when Nadia is in distress, and the practitioner says why: "Every time you go to that door, she learns that the way to get you is to scream, and every time she learns that, she has to scream louder, and she is spending all of her energy on it." The mother says: "But she needs me." And the practitioner says: "She needs you. She doesn't need you at the door while she's screaming. She needs you in the kitchen with a cup of tea and ten minutes of not needing anything from her."

**The assessment of the somatic presentation.** The practitioner arranges a medical review of the abdominal pain and arranges the screening for the physical consequences of the abuse, and the review finds nothing unaccounted for, and the practitioner says to Nadia: "Your body has been through something and it has kept

the record. The pain is not imaginary and it is not you being weak. What we are going to do is work with the body directly, and there is a person here who is very good at that, and I would like you to meet her." This is the referral to the somatic work of Chapter 43, and it is done in the first month, and it is the intervention that changes the trajectory of the case.

**The outcome of phase one.** At four months, Nadia is sleeping, is not dissociating in the sessions, has a safe adult in the school — the pastoral support worker, who has been trained in the grounding skills and who checks in with her daily by a specific agreed method — and the mother is no longer lying on the bathroom floor. The somatic work is running. The phase two work has not begun, and the practitioner says so to the referrer, in writing, with the criteria and the current status against each of them.

**The interpretation.** The case illustrates the central point of the chapter. The referral was for a protocol, and the protocol was the right protocol for a young person who was ready, and Nadia was not ready, and the failure of the previous therapies was a failure of the phase. The work of the first four months was not preparation in the sense of a preliminary; it was the treatment of a young woman whose nervous system was organised for survival and who had no capacity to be in a room. The mother was the decisive intervention, and the decision about the door was the specific act of clinical reasoning that made the rest possible.

# 7. Evidence and Research Support

## 7.1 The status of the evidence

**There is good evidence for the general principle** that the reduction of arousal precedes the cognitive work, and that the reduction is achieved through the body, and that a young person who is dysregulated cannot use the cognitive and the narrative techniques. This principle is well supported.

**The evidence for the individual grounding skills is growing and is positive.** The systematic reviews of the grounding, the stabilisation, and the self-regulation skills report positive effects on the symptoms of distress, on the physiological measures, and on the functional measures, and the most consistent findings are for the paced breathing, the sensory grounding, and the orienting.

**The evidence for the parent training element is the strongest part.** The parental component is the element with the best support, and the evidence for the parenting programmes in this population is good, and this is consistent with the developmental finding that the caregiver's regulation is the mediator of the young person's regulation.

**The evidence for the phase model as an integrated framework is thin**, and the most useful support is indirect: the comparative trials of the specific protocols, and the trials of the stabilisation-only treatments, which do show meaningful improvement in functioning.

**The clinical consensus considerably exceeds the empirical support**, and a student should be able to state this without embarrassment, because it is a true and important feature of the field.

## 7.2 Limitations of the evidence

**The trials are small and heterogeneous**, and the measures are frequently the self-reported distress measures.

**The fidelity of the stabilisation work is difficult to measure**, and the skill is delivered in different forms by different practitioners.

**The long-term outcomes are not well documented**, and the developmental question is unanswered.

**The studies are dominated by the adults**, and the paediatric evidence is smaller.

**The comparative evidence on the phase model against the direct provision of a specific protocol is absent**, and this is the most important missing study in the field.

# 8. Strengths and Limitations of the Stabilisation Work

## 8.1 Strengths

**It is the work that makes the rest possible.** This is its central and sufficient justification.

**It is teachable and it is portable.** A young person who has four or five grounding skills and a traffic light has something that works in the corridor, on the bus, and in the dining hall, and it does not require a therapy appointment.

**It is honest about the timeline.** The skills take weeks to months, and the young person can be told that, and this is a considerable relief to a young person who has been offered a cure in three sessions.

**It gives the young person control.** The traffic light and the self-monitoring move the regulation from the practitioner to the young person, and this is the objective of the phase.

**It addresses the ordinary functioning.** School, sleep, eating, and the relationships are the goals that the young person and the family want, and they are not the goals that the phase model privileges.

**It is the entry point for the somatic work.** The body-based work of Chapter 43 and the stabilisation work are the same work approached from two directions.

## 8.2 Limitations

**It can become a way of avoiding the work**, and this is the most serious limitation and the most common.

**It can be delivered in a way that is custodial.** A young person whose every action is monitored and whose every dysregulation triggers a response has not been given a skill; they have been given a more sophisticated supervision, and this is a real and documented failure mode in services that use the language of safety.

**The evidence for the individual skills is weaker than the practice assumes.**

**It does not address the source of the dysregulation.** If the threat continues, the skills will be used to survive it, which is what they are for, and the young person will remain dysregulated, and this is the correct behaviour and it is not a recovery.

**It can be infantilising.** The techniques were developed for adults and for young children, and the adaptation for an adolescent is a genuine design task, and a practitioner who teaches a sixteen-year-old a "safe place" in a bubble with a rabbit will lose the young person.

# 9. Cultural and Ethical Considerations

## 9.1 Culture and the body

**The body is not a universal language.** The somatic vocabulary of the stabilisation work — the grounding through the senses, the body scan, the attention to the body's signals — assumes that the body is a legitimate object of attention and that the young person has permission to attend to it. In some cultures and in some families, the body is a private and a shameful object, and the young person will not want to be asked where they feel it.

**Some of the grounding techniques are culturally inappropriate.** The "safe place" in the form of an imagined serene location is one cultural form; in some traditions, the safe place is a specific person, or a specific practice, or a specific place of worship, and a practitioner who insists on the internalised version has missed the point.

**The physiological claims are not universally applicable.** The breathing practices are drawn from a specific and largely Western scientific account, and a young person who has been taught a different breathing practice in their own tradition should be helped to adapt it rather than to abandon it.

**The movement-based grounding is the most broadly acceptable**, and it is often the entry point for a young person for whom the internal, verbal, and cognitive forms do not work.

### 9.2 Ethical considerations

**The relationship between the skills and the care.** A young person who has learned the grounding skills and who finds that the skills are used by the adults to manage them has been taught a tool for surviving the adults' interventions, and the practitioner should be alert to this.

**The risk of the custody model.** Every safety plan and every traffic light in a service is a piece of documentation, and a young person whose every action is logged has been placed in a form of soft containment, and the practitioner should ask routinely whether the documentation is a clinical tool or a control mechanism.

**The consent to the skills.** The young person should be able to decline a technique, and a young person who declines the body scan should not be pressed, and the alternatives should be offered.

**The handling of the disclosure during stabilisation.** A young person who discloses in the middle of a grounding exercise has disclosed, and the practitioner must know the reporting obligations and must not be so preoccupied with the technique that the disclosure is mishandled.

**The meaning of "safe".** A practitioner who tells a young person that the room is safe is making a promise, and a young person who has been abused in a room with an adult has good reason to doubt it, and the promise should be made carefully and kept absolutely.

**The work with the parents and the confidentiality of the young person's own experience.** The parent is coached in the same skills, and the young person should know what the parent has been taught and what the parent has been told, and the young person should have some private time with the practitioner.

**The prohibition on the use of the stabilisation phase to defer a safeguarding decision.** A young person who is still at risk requires a safeguarding response, and the stabilisation work is not a substitute for it.

## 10. Key Terms

**Key Terms at a Glance**

- **Stabilisation** — The phase of work in which the young person's capacity to be present, to think, and to feel is restored, and in which the specific capacities required for the processing work are established.
- **The four purposes of stabilisation** — To widen the window of tolerance, to build the capacity to remain present, to establish the working relationship, and to restore ordinary functioning.
- **Orienting to the here and now** — The five-four-three-two-one sensory grounding exercise, and the variants that orient to the internal sensations and to the temporal.
- **Grounding through the senses** — The script-based use of the sensory environment to anchor the young person in the present, and its contraindication where sensory detail is activating.
- **Paced breathing** — The lengthening of the exhalation to increase the vagal tone and reduce the arousal, and the technique to use in the sympathetic state.
- **The contraindication of the breathing in the dorsal vagal state** — The deepening of the exhalation deepens the shutdown, and the orienting and movement are required instead.
- **The safe place** — A concrete, sensory, personally meaningful location, taught in detail and used as the resourcing intervention.
- **The container** — The imagined receptacle into which the young person places the overwhelming material, usually taught in the drawing.
- **The body scan** — The movement of attention through the body with the reporting of what is noticed, used both in the stabilisation work and in the completion of the autonomic component of a memory.
- **The contraindication of the body scan** — Its use with a young person with a history of bodily abuse, and the movement-based alternative.
- **Movement-based grounding** — The large, undemanding physical discharge and the orienting through movement, the most broadly acceptable form of the grounding work.
- **The orienting through movement** — The up-and-down eye movement exercise with a moving object, derived from the EMDR literature.
- **Time travel to a safe memory** — The recollection of a real and specifically pleasant memory as an orienting and regulating practice, and the requirement that the memory be real and checked.
- **Asking for help and saying no** — The two interpersonal skills taught in the stabilisation phase, and the requirement that the requests be met and the declines honoured.
- **The traffic light** — The three-colour self-monitoring scheme in which the young person locates their own arousal and knows what they need at each level.

**Key Terms at a Glance (continued)**

- **The movement of the regulation to the young person** — The objective of the stabilisation phase, and the criterion by which its completion is judged.
- **The phase-oriented framework** — The management structure in which the work is determined by the young person's state rather than by the type of trauma, with the phases and the transition criteria.
- **The transition criteria** — The explicit conditions for moving between the phases, and the requirement that they be recorded.
- **The transition backwards** — The return to phase one on the deterioration of the young person's functioning, and the formulation that the deterioration requires.
- **The phase-specific pathways** — The separate procedures, documentation, and review criteria that characterise each phase in a service framework.
- **The false dichotomy** — The two failure modes of a service that does only stabilisation, and a service that processes regardless of readiness.
- **The four presentations for stabilisation** — The dissociating young person, the hyperaroused young person, the young person with a persistent somatic presentation, and the young person in an unstable placement.
- **The co-regulation principle** — The finding that the caregiver's regulation capacity mediates the young person's, and the reason the parent is taught the same skills.
- **The generalisation plan for the skills** — The deliberate practice of the skills in the contexts in which the young person will need them, and the reason the skills are portable.

## 11. Chapter Summary

Stabilisation is the necessary and unglamorous work that precedes everything else, and its central proposition is that a young person's capacity to be in a relationship, to think, and to feel is regulated by the body, and that the body can be taught to be more regulated. The chapter set out the four purposes of stabilisation — widening the window of tolerance, building the capacity to remain present, establishing the working relationship, and restoring ordinary functioning — and distinguished stabilisation from the processing work, from supportive counselling, from symptom suppression, and from a prelude that can be skipped.

The evidence was presented accurately: good support for the general principle, a growing and positive evidence base for the individual skills, the strongest support for the parent training element, thin support for the phase model as a package, and a clinical consensus that considerably exceeds the empirical support.

The core skills were described in detail with their mechanisms, their teaching procedures, and their contraindications: the orienting skills to the here and now, to the internal sensations, and to the temporal; the sensory grounding, with its contraindication where sensory detail is activating; the paced breathing, with its physiological rationale and with the crucial caution that it must not be used in the dorsal vagal state; the safe place and the container; the body scan, with its two uses and its contraindication in the case of bodily abuse; the movement-based grounding, including the orienting through movement; the time travel to a safe

memory, with the requirement that the memory be real and checked; the two interpersonal skills; and the traffic light, with the observation that its value is that it moves the responsibility for the regulation from the practitioner to the young person, which is the criterion of the phase's completion.

The phase-oriented approach was described with its rationale, its three phases in practice, the phase transitions as clinical decisions, and the management framework with its phase-specific pathways, its phase-specific staff, its measurement, and the avoidance of the false dichotomy.

The developmental modifications were described: the skills are taught to the young person and not to the practitioner, the language is the young person's own, the parent is taught the same skills, the generalisation is planned, and the developmental order matters. The four presentations were described and the four limits stated, with the risk that the skills become a way of avoiding the work identified as the most serious.

The case of Nadia demonstrated the chapter's central point. The referral was for a protocol and the protocol was appropriate for a young person who was ready, and Nadia was not ready, and the failure of the previous therapies was a failure of the phase. The work of the first four months was not preparation but the treatment of a young woman whose nervous system was organised for survival, and the decisive intervention was with the mother, and the specific decision about the door was the act of clinical reasoning that made the rest possible.

The evidence was summarised with its limits, and the strengths and limitations were set out, with the custodial failure mode and the infantilisation risk named.

The cultural analysis addressed the body as a culturally constructed object, the cultural forms of the safe place, the limits of the universality of the physiological claims, and the relative acceptability of the movement-based grounding. The ethical section addressed the relationship between the skills and the care, the risk of the custody model, the consent to the skills, the handling of a disclosure during a grounding exercise, the meaning of the promise of safety, the transparency of the parent work, and the prohibition on using the stabilisation phase to defer a safeguarding decision.

## 12. Review and Discussion Questions

**Review and Discussion Questions**

1. State the central clinical proposition of the stabilisation work.
2. State the four purposes of stabilisation.
3. Distinguish stabilisation from the processing work, from supportive counselling, from symptom suppression, and from a prelude.
4. Summarise the evidence for the stabilisation work and state the two places in which the consensus exceeds the evidence.
5. Describe the three orienting skills and their specific use.
6. Describe the sensory grounding and state its contraindication.
7. Explain the physiological rationale of the paced breathing and state its contraindication.
8. Describe the safe place and the container, and distinguish them.
9. Describe the body scan, its two uses, and its contraindication.
10. Describe the movement-based grounding and the orienting through movement.
11. Describe the time travel to a safe memory and its requirements.
12. Describe the two interpersonal skills of the stabilisation phase.
13. Describe the traffic light and explain why it is the criterion of the phase's completion.
14. Explain the rationale of the phase-oriented approach.
15. Describe the three phases in practice and the phase transitions as clinical decisions.
16. State the five features of the phase-oriented management framework and the false dichotomy it avoids.
17. State the five developmental modifications for the stabilisation work.
18. Describe the four presentations for stabilisation.
19. State the four limits of the stabilisation work.
20. Describe the case of Nadia and state the three features of it that generalise.
21. Summarise the status of the evidence and its five limitations.
22. State the six strengths and the six limitations of the stabilisation work.
23. Explain the four cultural considerations for the body-based work.
24. State the seven ethical requirements for the stabilisation phase.

## 13. Practice Activities

**Practice and Application**

### Activity 40.1 — The Personal Grounding Inventory (90 minutes, field-based)

In a placement, work with one young person to build their own grounding inventory, and record the following: their safe place, with sensory detail; their five preferred sensory anchors; their preferred movement; their best genuine safe memory; their early warning signs; their traffic light descriptions; and the two people they can ask for help. The inventory becomes a document they own, and the exercise teaches that the inventory is built from the young person's own material and not from the practitioner's.

### Activity 40.2 — The Skill Rehearsal (75 minutes, triadic)

One student plays a fifteen-year-old in a state of high arousal; one plays the practitioner; one observes. The practitioner must bring the arousal down without talking about its content, using only the body's language. The observer's task is to record every intervention that the practitioner makes and to mark the point at which the young person's state changes. The exercise teaches the most important thing in the chapter, which is that the intervention in the sympathetic state is not linguistic.

### Activity 40.3 — The Phase Criteria Audit (60 minutes, individual)

Take a case and write out the criteria for moving from phase one to phase two, marking each as met, partially met, or not met, with the evidence. Then write the three specific interventions that would move the two that are not met from "not met" to "partially met". The exercise is the discipline of the phase model, and it also reveals how easily a practitioner drifts into phase two because the pressure to do something is stronger than the discipline.

### Activity 40.4 — The Custody Audit (60 minutes, small group)

Take a real service's safety plan, traffic light, or behaviour chart and audit it from the young person's point of view. For each element, ask: does this give the young person a skill, or does it give the adults a record? Then rewrite the elements that fail the test, and identify what would have to change in the service for the rewrite to be possible. The second half of the exercise is the organisational work of Chapter 58 and it is the part that matters most.

## 14. Annotated Reading Pathways

**For the body.** Read van der Kolk (2014), Ogden's sensorimotor psychotherapy, and the trauma and the body literature. These are the theoretical basis of the body-based work and they are more convincing than the technique manuals.

**For the skills.** Read the stabilisation sections of the Child and Family Traumatic Stress Intervention manual and the Linehan skills repertoire, and read Cutting's work on the neuroscience of grounding, which is the most useful single paper on the specific techniques.

**For the phase model.** Read the phase model chapters in the standard clinical texts and the guidelines for the treatment of PTSD, and read the child and adolescent protocols of the specific approaches.

**For the parent work.** Read the parenting and co-regulation literature and the emotion coaching material from Chapter 37. The parent component is the evidence-supported core of the stabilisation work.

**For the critique.** Read the critical literature on the custodial drift of trauma services and on the over-use of safety plans. The field has been subjected to serious criticism on these grounds and the criticism has produced some of the better practice standards.

# Practice Laboratory and Extended Worked Example

This laboratory turns **Stabilisation, Grounding, and Phase-Oriented Work** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is skills for the first phase of trauma treatment and the maintenance of stability between sessions. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is safety, regulation, emotion, memory, relationships, and paced therapeutic work. The mechanism to keep in view is how threat, arousal, avoidance, meaning, and relational safety shape what a young person can feel, remember, and learn. The characteristic professional risk is moving into traumatic material before stabilisation, confusing calm with shutdown, or making disclosure the price of care. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

## A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in stabilisation sessions, trauma-informed schools and services, caregiver work, and specialist treatment pathways, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and**

**eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Tunde is fifteen and is seen in a community adolescent clinic for school avoidance and rising panic. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Tunde's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Tunde explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on safety, regulation, emotion, memory, relationships, and paced therapeutic work. The first intervention is deliberately modest. Tunde chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Tunde has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Tunde can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Stabilisation, Grounding, and Phase-Oriented Work

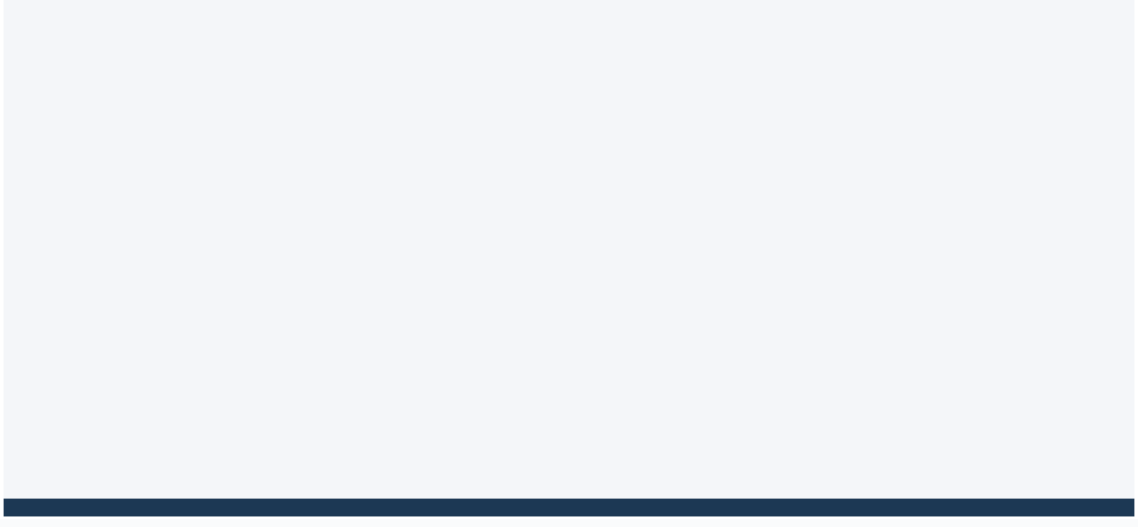
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Stabilisation, Grounding, and Phase-Oriented Work** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Stabilisation, Grounding, and Phase-Oriented Work** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Stabilisation, Grounding, and Phase-Oriented Work**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Stabilisation, Grounding, and Phase-Oriented Work to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 41

# Interpersonal Psychotherapy for Adolescents

Klerman's model, the social problem-solving curriculum, and the treatment of adolescent depression.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain the origin of interpersonal psychotherapy and describe the clinical problems that produced it.
- State the four problem areas of the model and describe each in detail.
- Describe the three phases of treatment and the specific tasks of each.
- Describe the techniques of the model, including the exploration, the clarification, the dialogue with the significant other, and the enactment.
- Apply the model to the treatment of adolescent depression and to a case involving an adolescent interpersonal difficulty.
- Critically evaluate the cultural and ethical dimensions of interpersonal psychotherapy with young people, including the questions of the model's origins and of the limits of a dyadic model with a young person who is at risk.

## Chapter Overview

Interpersonal psychotherapy was developed in the 1970s by Gerald Klerman and colleagues, and it was designed for a population that the psychotherapies of the time served badly: people with depression whose difficulties were not primarily cognitive, people for whom the depression had become embedded in a set of strained relationships, and people for whom a long, exploratory, and interpretative treatment was not feasible.

The model's proposition is that **depression is maintained by problems in the relationships**, and that the treatment is the resolution of those problems. The depression is not treated directly and it is not interpreted; the relationships are treated, and the depression improves as the relationships improve.

This makes it a distinctive proposition in this book, and it is worth noticing what it shares with the systemic approaches of Part V and what it shares with the behavioural approaches of Part IV. It shares with the systemic approaches the view that the problem is in the interaction rather than in the individual. It shares with the behavioural approaches the view that the targets should be specific and observable. And it shares with the cognitive approaches the view that the young person's own account of their situation is the clinical material.

The adaptation of the model for adolescents, developed in the 1990s and tested in a large multisite trial, is the most thoroughly evaluated adolescent psychotherapy in the literature for adolescent depression, and it is a treatment that a school counsellor can deliver with a modest amount of training and a good manual.

## 1. Historical Context

### 1.1 The origin

The model was developed at the Massachusetts General Hospital and its origin was partly pragmatic. The 1970s psychopharmacological trials had established that antidepressants worked, and the clinical problem was that the improvement was partial, that the relapse rate was high, and that the patients were not engaged in any long-term psychological work.

The intervention that was designed to address these problems was not a new theory of depression but a **time-limited, focused, and practical treatment** that addressed the interpersonal situations in which the patient's depression was embedded. The manual was short by the standards of the time, the treatment was twelve to sixteen weeks, and the goals were specific, current, and changeable.

### 1.2 The development of the model

The theory is described in three propositions, and a student should be able to state all three.

**Depression is a disorder of the interpersonal sphere.** The mood disorder is a response to the way in which the person's relationships are arranged, and the interpersonal difficulties are the target rather than the context.

**The role of the therapist is explicit.** The therapist is not a passive listener, not an interpreter, and not a collaborator in the exploration of the unconscious. The therapist takes an active, teaching, problem-solving role, and the relationship is warm and personal but structured, and the structure is what makes the treatment safe with a young person.

**The problems are the target and the mood improves as a consequence.** The therapist does not attempt to make the patient feel better. The therapist attempts to resolve the interpersonal problems, and the improvement in the mood is the outcome of that work, and it is a reliable outcome, and the model predicts it.

### 1.3 The evidence and the extensions

The model's evidence base is among the best in the field, and the extensions are numerous: interpersonal psychotherapy for depression, for bulimia, for social anxiety, for the PTSD, for the perinatal depression, for the grief, and for the adolescent depression.

The adolescent adaptation, which is the subject of this chapter, was developed in the 1990s and was tested in a large multisite randomised controlled trial, the Treatment for Adolescents with Depression Study, in which interpersonal psychotherapy for adolescents was one of the two treatments tested against a placebo control. The interpersonal psychotherapy arm produced significant improvements in the depression, and the improvements were comparable to those of the other active treatment, and the results are among the strongest in the adolescent depression literature.

## 2. The Four Problem Areas

### 2.1 The four areas

The model specifies four problem areas, and a student should be able to name them and describe the specific interventions associated with each.

**Grief and loss.** The death of a person to whom the young person was close, and the loss is broader than death: the loss of a relationship, the loss of a role, the loss of a place, the loss of a future. The interventions are the **complicated grief** procedure, in which the therapist works with the young person to differentiate the loss from the other things that have changed, and to restore the other things.

**Disputes and conflicts.** The relationships in which the young person is in conflict with others, most often with a parent, a sibling, or a peer. The interventions are the **dispute resolution** procedure, in which the young person is helped to identify the specific dispute, to identify the specific point of disagreement, and to

work out what specifically is being asked for and what specifically is being given.

**Deficits in role transition.** The changes of role that are developmental: leaving school, moving up, a friend moving away, a parent separating, a move to a new country, the end of a relationship, the first job. The interventions are the **role transition** procedure, in which the young person is helped to identify the roles that have been lost and the roles that are being taken on, and to explore the new role and to find the new supports.

**Deficits in social skills and interpersonal deficits.** The young person's difficulty in the relationships themselves: the difficulty in making and keeping friends, the difficulty in asserting, the difficulty in engaging with a wider network, the withdrawal. The interventions are the **social skills** and **relationship enhancement** procedures, in which the young person is helped to develop the specific skills and to practise them in role.

## 2.2 The assessment

The assessment in interpersonal psychotherapy is itself a therapeutic instrument, and the structure of the assessment is what the treatment is built on.

**The diagnostic assessment.** The diagnosis, the history, the current medication, the medical history, the current safety assessment, and the developmental and social history.

**The interpersonal inventory.** This is the distinctive instrument of the model and it is completed in a specific way: the young person is asked to name the people in their life, one at a time, and for each person to rate a set of dimensions. The dimensions are the areas in which the difficulties might lie, and the young person rates each of them on a scale, and the ratings identify the problem areas.

The dimensions are: the grieving and bereavement dimension, which asks about the loss; the disputes dimension, which asks about the conflicts; the role transition dimension, which asks about the changes; the social skills dimension, which asks about the social functioning; and the interpersonal deficits dimension, which asks about the relationships that are going badly.

**The most important person.** The inventory identifies the most important person in the young person's life, and this person becomes the focus of the treatment. In the adolescent adaptation, the most important person is usually a parent, and the treatment is therefore usually a treatment of the parent–adolescent relationship, and this is the single most important structural feature of the adolescent model.

**The specific interpersonal problem.** The interpersonal inventory ends with the identification of the specific interpersonal situation that is the current focus of the treatment, expressed as a concrete, in-the-present, and behaviourally specified request. "I want my mother to let me stay out until eleven on Fridays" is a specific interpersonal problem. "My relationship with my mum is bad" is not.

## 2.3 The role and the domains

The **role** of the young person in their own difficulty is the most clinically valuable single concept in the model, and it is worth a student's attention.

The role is asked in a specific form: "When you are with your mother and she is doing the thing that you hate, what do you do? What do you feel? What do you want?" And the three answers — the behaviour, the feeling, and the want — are then related to each other. The therapeutic work is in the relation between the three.

The clinical finding is that young people in distress frequently report a discrepancy: a role that does not match their own view of themselves, or an unsuccessful strategy, or a mismatch between what they want and what they do. The **discrepancy** is the target.

The **domains** are the specific situations in which the role and the discrepancy are observed, and the domains are agreed with the young person in the first session. In the adolescent adaptation, the domains are typically the school, the peer group, and the family, and the work moves through them in a planned sequence, usually beginning with the peer group and moving to the family.

# 3. The Three Phases

## 3.1 The structure

**Phase one: the initial phase.** Weeks one to four. The tasks are: to establish the working relationship and the contract; to provide the **education about depression**, which is a specific and empirically supported intervention in its own right; to complete the interpersonal inventory; to set the agenda for the treatment; to identify the specific interpersonal problem; to identify the domains; and to begin the work on the role and the discrepancy.

The **education about depression** deserves particular attention. It is a structured component in which the young person is told, in plain language, what depression is, what it does, what it does not mean, and what the treatment is going to do, and it has a measurable effect in its own right, and it works by normalising the experience and by removing the attribution of the depression to a personal or moral failing. The content includes: the symptoms; the prevalence; the biological and the psychological and the social contributions; the fact that it is not a character defect; the fact that it is not caused by a single event; and the fact that it is treatable. A student should be able to state this list.

**Phase two: the middle phase.** Weeks five to eleven. The tasks are the focused work on the specific interpersonal problem and on the domains, and the use of the specific techniques.

**Phase three: the termination phase.** Weeks twelve to sixteen. The tasks are: to consolidate the changes; to review the progress; to identify the remaining problems and to work on them; to review the coping skills; to make the plans for the termination; and to arrange the follow-up. The termination phase is not a summary; it is a phase with its own agenda and its own tasks.

# 4. The Techniques

## 4.1 Exploration

**Exploration** is the first of the four core techniques, and it consists of three elements.

**The exploration of the interpersonal problem.** The therapist helps the young person to specify the problem in behavioural and situational terms, and the specification proceeds by asking: who is involved; what is being said; what is being done; how often; with what consequence; and what the young person wants to be different.

**The exploration of the feelings.** The young person is helped to identify the feelings, and the specific word for the feeling is elicited, and the examination of the discrepancy between the feeling and the behaviour is begun.

**The exploration of the wishes and the wants.** The young person is asked what they want from the situation, and the question is asked separately from the feelings, and the two are then compared, and the comparison is frequently the moment of insight in the session.

## 4.2 Clarification

**Clarification** is the second technique, and it is the technical heart of the model. The therapist asks the young person to describe the interpersonal situation in specific terms, and the young person is prompted to give **details**: who was there, what was said, in what order, what the other person actually said, what the young person actually said, and what happened next.

The purpose of the clarification is to move the problem from a global and abstract description to a specific and observable event, and the effect of this is often immediate and often surprising to the young person, because a global description of a hopeless situation is transformed into a sequence of specific, and sometimes tractable, events.

The therapist's stance during the clarification is active, curious, and directive: the therapist asks, "Can you tell me exactly what your mother said?" and "And what did you say back?" and "And then what did she do?"

## 4.3 The dialogue with the significant other

The third technique is the **interpersonal dialogue**, and it is a specific behavioural procedure rather than a general encouragement to talk.

**The procedure.** The young person and the therapist construct, in the session, a script of what the young person would like to say to the significant other. The script is written down, word by word, and it is rehearsed in the session, and it is then used in the real situation between the sessions.

**The construction of the script.** The script is built from the specific problem, and the questions are: what do you want to say; what do you want them to do differently; what are you afraid will happen; and what would you say if you were not afraid.

**The rehearsal.** The rehearsal is in the session, and it is the most useful part of the technique for a young person, because it is the first time the words have been said out loud, and the young person discovers what the words sound like, and the therapist helps to revise them until they are usable.

**The practice and the follow-up.** The young person tries the script in the real situation, and the next session begins with what happened.

The clinical significance is that this technique puts the young person in the position of making a specific, specified request to a person who matters, in a form that has been rehearsed, and the effect on the relationship is often substantial, and the effect on the young person's self-efficacy is often the more important effect.

## 4.4 The enactment

The fourth technique is the **enactment**, in which the young person and the therapist stage a role-play of the problematic situation.

**The procedure.** The young person plays the significant other and the therapist plays the young person, and the scene is then reversed. The purpose is to give the young person the experience of being on the other side,

and the experience is often revelatory: a young person who believes that their mother does not listen discovers, in the enactment, that they are not listening either, and the discovery is available in a way that a direct argument would not have made it.

**The cautions.** The enactment is a technique from the psychodynamic tradition and it carries the risks of that tradition: it can be experienced as an intrusion, it can overwhelm a young person with a fragile sense of self, and it should not be used with a young person who is in the early phase of the work or who is very unstable. The therapist's competence in the technique is the precondition for its use, and the model's training in the technique is rigorous.

### 4.5 The other techniques

**The encouragement and the support.** The therapist gives direct, specific, and earned praise, and the practice of noticing and naming the young person's successes is a specific technique with specific rules.

**The symptom monitoring.** The young person monitors their own mood daily, on a simple scale, and brings the record to the session. The technique has an effect in its own right and it is a useful device for the beginning of a session, because it opens the conversation with something the young person has produced.

**The homework.** The interpersonal psychotherapy session is prepared with the agenda, and the homework is the practice of the specific technique between the sessions.

# 6. Interpersonal Psychotherapy with Children and Adolescents

## 6.1 Why the adolescent adaptation works

The adolescent adaptation works because depression in adolescence is seldom only an internal event. It is lived in bedrooms, classrooms, group chats, changing rooms, family meals, examinations, friendship ruptures, first romantic attachments, and the painful comparison between the young person's actual life and the curated lives of peers. A treatment that asks who matters, what has changed, what is disputed, and what the young person needs from the most important relationship speaks directly to the adolescent's world.

Four adaptations distinguish the adolescent model from the adult model.

**The developmental assessment is more extensive.** Puberty, school transitions, examinations, cognitive development, peer hierarchy, identity formation, digital communication, autonomy, and family dependence must all be assessed. Two young people of the same chronological age may be at very different developmental levels.

**The family is structurally involved.** The adolescent usually still lives at home, depends on adults for transport, money, permission, food, and school decisions, and cannot simply implement an interpersonal plan alone. Parents or carers are therefore brought into psychoeducation, safety planning, and selected joint sessions, while preserving a confidential individual space for the young person.

**The school is an interpersonal system.** Teachers, tutors, attendance officers, coaches, school nurses, and safeguarding leads may all hold pieces of the problem. A dispute that appears to be between mother and daughter may be maintained by a timetable, a seating plan, a public sanction system, or an unrecognised learning difficulty.

**The language is concrete.** Abstract words such as abandonment, transition, and ambivalence are translated into observable exchanges: who texted, who replied, who walked away, who raised their voice, who apologised, who was left out, and what happened next.

## 6.2 Assessment in practice

A good IPT-A assessment usually takes two or three sessions and produces four documents.

First, a **symptom and risk formulation**: diagnosis where appropriate, severity, duration, sleep, appetite, energy, concentration, anhedonia, irritability, self-harm, suicidal thinking, substance use, medical factors, medication, and protective factors.

Second, an **interpersonal inventory**: the important people, rated for closeness, conflict, reliability, support, disappointment, and change.

Third, a **problem-area formulation**: grief, dispute, role transition, or interpersonal deficit, stated in one paragraph and agreed with the young person.

Fourth, a **treatment contract**: number and frequency of sessions, who will be involved, confidentiality limits, safety arrangements, measures, and review dates.

The young person should leave assessment knowing what will happen next. Uncertainty is itself a burden for a depressed adolescent, who may already experience time as slow, effort as pointless, and help as unlikely to arrive.

## 6.3 The four problem areas with adolescents

**Grief.** Adolescent grief is often disenfranchised. The young person may be expected to return to school quickly, may not have been included in rituals, may grieve a grandparent while adults describe the death as expected, or may grieve a parent while also feeling anger, relief, guilt, or disloyalty. IPT-A distinguishes grief for a person from grief for a former self, home, school, friendship group, or imagined future.

**Role disputes.** These are the commonest presentations. A parent wants obedience and safety; the adolescent wants autonomy and trust. A teacher wants compliance; the student wants dignity and escape from humiliation. Two friends want loyalty; a third wants inclusion. The task is not to decide who is right, but to specify the non-reciprocal expectations and negotiate a tolerable next step.

**Role transitions.** Starting secondary school, moving schools, changing friendship groups, parents separating, a new sibling, migration, leaving care, examination failure, injury ending sport, pregnancy, coming out, and the transition from child to adult services are all role transitions. The old role is mourned, the new role is explored, and supports for the new role are built.

**Interpersonal deficits.** Some adolescents are chronically isolated, socially anxious, repeatedly rejected, or unable to read interpersonal cues. The work is slower and more skills-based: initiating contact, joining a group, tolerating silence, repairing after embarrassment, ending exploitative relationships, and building a small number of sustainable relationships rather than pursuing popularity.

## 6.4 Techniques translated into adolescent practice

**Communication analysis** breaks a painful exchange into a chain: trigger, interpretation, feeling, words, tone, response, consequence. A mother says, “You haven't started,” meaning concern about revision; the daughter hears, “You are lazy”; she feels shame; she replies, “Leave me alone”; the mother hears rejection; she threatens to remove the phone; the daughter withdraws; both feel unheard. The analysis makes the sequence visible without turning either person into the villain.

**Decision analysis** lists options, advantages, disadvantages, likely responses, and the young person's values. It is especially useful where every option feels intolerable.

**Role play** is used sparingly and consensually. The young person rehearses asking a teacher for an extension, telling a friend that a joke went too far, or informing a parent that constant location tracking feels like distrust. Rehearsal must never become a performance for the therapist's satisfaction.

**Affect work** links feeling to interpersonal event. The question is not merely “How depressed are you?” but “When your friend left you on read for six hours, what happened inside you, what did you conclude, and what did you do next?”

**Clarification** tests vague statements. “Everyone hates me” becomes who, when, what was said, what was inferred, and what alternative explanations exist. Unlike cognitive disputation, the goal is not to prove the thought false; it is to recover the interpersonal facts.

### 6.5 Working with parents and carers

Parents should not become co-patients by default, nor should they be excluded as obstacles. A useful structure is:

1. A parents-only psychoeducation meeting near the beginning.
2. Individual sessions with the adolescent as the main treatment space.
3. One or two planned joint sessions where a specific communication is rehearsed and attempted.
4. A termination meeting that reviews warning signs and relapse prevention.

The practitioner explains that adolescent confidentiality has limits where safety is concerned, but that ordinary disclosures about friends, sexuality, embarrassment, anger at parents, and ambivalence about treatment will not be relayed verbatim. If a parent demands a transcript, the alliance will usually collapse.

### 6.6 IPT-A in schools

Schools are natural settings for IPT-A because the interpersonal problem often occurs there and because attendance provides routine monitoring. School delivery requires clear boundaries: the counsellor is not a disciplinary officer, session content is not used for behaviour management, and outcome information shared with staff is limited to what the young person has agreed, except where safeguarding overrides confidentiality.

A school-based formulation might focus on a dispute with a teacher, grief after a friend moves away, role transition after exclusion, or social isolation following bullying. The counsellor must be alert to institutional causes. If a young person is repeatedly humiliated by public behaviour charts, private shaming, racist discipline patterns, or inaccessible work, interpersonal therapy must not be used to teach adaptation to an unjust environment. Consultation and advocacy may be required alongside therapy.

## 7. Case Illustration: The Girl Who Stopped Answering

**Presentation.** Amara is fifteen. Her grades have fallen, she sleeps until midday at weekends, and she has stopped replying to messages from her closest friend. Her mother describes her as “withdrawn and oppositional”. Her father, from whom her mother separated eight months ago, describes her as “fine when she's with me”, which increases the mother's sense of failure.

**Assessment.** Amara's most important person is her friend Sofia, not either parent. Four months earlier, Sofia began spending most breaks with a new group. Amara interpreted delayed replies as proof that she had been replaced. She stopped initiating contact to avoid further rejection, then felt guilty for being distant, then became angry when Sofia accused her of “being weird”. The primary problem area is a role dispute intertwined with a role transition: the friendship has changed, and Amara has no script for renegotiating it.

A secondary dispute exists at home. Her mother checks her phone location repeatedly after Amara stayed out late once. Amara experiences checking as surveillance; her mother experiences Amara's silence as danger. Each protects herself in a way that frightens the other.

**Formulation shared with Amara.** “Your depression worsened when the friendship changed. You protected yourself by going quiet, but the quiet made you feel more cut off and more certain that Sofia didn't care. At home, the more worried your mum becomes, the more she checks; the more she checks, the less you tell her. The treatment will focus first on the friendship dispute, then on a specific conversation with

your mum about safety and privacy." Amara agrees, but asks that her mother not be told details about Sofia.

**Middle phase.** Communication analysis reconstructs one exchange in painful detail. Sofia wrote "can't today sorry". Amara concluded, "She's done with me." She felt shame, waited three days, and replied with a joke that sounded sarcastic. Sofia replied, "why are you being like this?" Amara left the message unopened for a week.

The therapeutic work does not declare Amara's interpretation irrational. It asks what else "can't today" might mean, what Amara wanted Sofia to know, and what a direct communication would risk and make possible. Amara identifies the wish beneath the sarcasm: "I miss how it was, but I don't want to beg."

A script is drafted, shortened, and rehearsed:

> *"I know things have changed and I don't expect everything to be the same. I miss talking to you. When I go quiet, it's because I think I'm bothering you, not because I don't care. Can we just have lunch on Thursday and see how it is?"*

Amara sends a shorter version by text rather than speaking it, which the therapist accepts. Negotiating the medium is part of adolescent practice; insisting on face-to-face purity would have privileged technique over use.

Sofia replies warmly but not effusively. They meet once, awkwardly. The friendship does not return to its previous intensity, but it becomes honest. Amara grieves the old exclusivity while forming a second connection through a lunchtime art group. Depression improves not because the original relationship is restored, but because the interpersonal world becomes larger than one threatened bond.

**Family session.** A joint session addresses location checking. The therapist prevents a general trial about trust. The specific request is negotiated: location sharing during journeys to and from a Saturday activity, no continuous checking at home, a text on arrival, and review after three weeks. Amara agrees to answer a safety text within thirty minutes or explain later why she could not. Her mother agrees not to use location data to interrogate ordinary movements. The agreement is written down.

**Termination.** Amara's mood has improved, sleep is more regular, and attendance is restored. The relapse plan identifies interpersonal warning signs: not replying for more than two days, cancelling all social contact, interpreting silence catastrophically, and escalating phone conflict. She writes her own plan in her own words: "Tell one person early, even if it's just: I'm going quiet because I'm embarrassed, not because I don't care."

**Interpretation.** The case shows IPT-A's discipline. The therapist did not excavate Amara's childhood, challenge every negative thought, or instruct the mother to be less anxious. The treatment selected a focal interpersonal problem, reconstructed events in sequence, clarified feelings and wishes, rehearsed a real communication, reviewed its actual outcome, and expanded the social field. The depressive symptoms improved as the interpersonal impasse loosened.

## 8. Evidence and Research Support

Interpersonal psychotherapy has a strong adult evidence base for major depression and is recommended in several clinical guidelines. The adolescent adaptation has been evaluated in school-based and clinic-based randomised trials, including studies by Mufson and colleagues, showing greater reduction in depressive

symptoms and better social functioning than usual care or supportive comparison conditions in several samples.

The Treatment for Adolescents with Depression Study placed youth depression treatments in a large comparative context, although IPT-A was not simply interchangeable with the specific interventions tested there and should not be misdescribed. Later trials and systematic reviews support IPT-A as a credible first-line psychosocial treatment for adolescent depression, particularly where the presentation is closely linked to grief, disputes, transitions, or social deficits.

Evidence is strongest for mild to moderate adolescent depression and for delivery over approximately twelve to sixteen sessions by trained practitioners with supervision. Evidence is weaker for severe depression with acute suicidality, psychosis, bipolar disorder, severe trauma symptoms, eating disorders, substance dependence, or neurodevelopmental conditions requiring substantial adaptation. IPT-A can be part of care in such cases, but rarely the whole of care.

Outcome measurement should include depressive symptoms, functioning, school attendance, interpersonal functioning, self-harm risk, and the young person's own goals. Symptom improvement without restored participation may be insufficient; conversely, a modest symptom change with return to school, friendship, and family life may be clinically meaningful.

Limitations include variability in manual fidelity, dependence on verbal reflection, cultural assumptions about direct communication, and under-representation of some ethnic, linguistic, disabled, care-experienced, and LGBTQ+ populations in trials. Practitioners should therefore treat the model as evidence-informed, not evidence-proof.

## 9. Strengths and Limitations

### Strengths

**Developmental relevance.** Adolescent depression is often organised around belonging, autonomy, peer status, family conflict, and transitions.

**Clarity.** The focal problem area gives treatment a map and prevents aimless exploration.

**Non-blaming language.** A dispute is not a defective personality; a transition is not weakness; grief is not pathology merely because it hurts.

**Practical skills.** Communication analysis, rehearsal, and decision analysis create actions the young person can test.

**Family and school compatibility.** The model can coordinate individual, parental, and school work without collapsing confidentiality.

### Limitations

**It may understate internal processes.** Rumination, trauma memory, obsessive-compulsive mechanisms, psychosis, neurodevelopmental differences, and biological illness may require other interventions.

**Direct communication is not universally safe or culturally congruent.** In some families, direct challenge to an elder is disrespectful or dangerous. Indirect communication, mediation, written messages, or involving a trusted relative may be better.

**It can individualise institutional harm.** Bullying, racism, poverty, inaccessible schooling, and unsafe housing cannot be resolved by asking the young person to communicate more skilfully.

**It depends on a focal problem.** Diffuse distress, severe avoidance, dissociation, or inability to identify relationships may require stabilisation or another approach first.

## 10. Cultural and Ethical Considerations

Cultures differ in whether feelings are named directly, whether family decisions are individual or collective, how grief is expressed, what privacy from parents means, and how conflict with authority is handled. The practitioner must ask rather than assume: Who should be involved? What may be said directly? What would shame or endanger the young person? What forms of help are trusted?

Ethically, the practitioner must protect confidentiality while meeting safeguarding duties; include parents without surrendering the adolescent's voice; avoid becoming an agent of school discipline; and monitor risk throughout rather than assuming that a relational formulation explains everything. Consent and assent should be revisited when parents join sessions, when school staff are consulted, or when digital communication is reviewed.

Particular care is needed with LGBTQ+ adolescents. A dispute with parents may involve rejection of identity, concealment for safety, or conflict over names, pronouns, clothing, friendships, or faith-community participation. The therapist must not frame acceptance of the young person's humanity as a negotiable communication problem, nor disclose identity information without consent except where a lawful safeguarding duty requires action. Safety planning and affirming support take precedence over generic dispute resolution.

## 11. Key Terms

**Key Terms at a Glance**

- **Interpersonal psychotherapy (IPT)** — A time-limited treatment that links mood symptoms to grief, disputes, role transitions, and interpersonal deficits.
- **IPT-A** — The adolescent adaptation of interpersonal psychotherapy, incorporating developmental assessment, family involvement, and school context.
- **Interpersonal inventory** — A structured review of important relationships and the difficulties within them.
- **Role dispute** — A relationship impasse involving non-reciprocal expectations.
- **Role transition** — Distress associated with moving from an old social role to a new one.
- **Interpersonal deficit** — A persistent difficulty forming or maintaining satisfying relationships.
- **Communication analysis** — Detailed reconstruction of an interpersonal exchange to identify triggers, interpretations, feelings, responses, and consequences.
- **Decision analysis** — Structured comparison of options, consequences, values, and likely interpersonal responses.
- **Affect–event link** — The connection between a change in mood and a specific relational event.
- **Focal problem area** — The interpersonal domain selected as the primary target of treatment.

## 12. Chapter Summary

Interpersonal psychotherapy offers adolescents a focused, humane, and practical treatment that connects depression to the relationships in which it is lived. Its four problem areas—grief, disputes, transitions, and interpersonal deficits—translate complex suffering into workable questions. Who has been lost? What expectation is contested? What role has changed? What relationship capacity needs building?

The model does not ask the young person merely to think differently or behave differently. It asks what happened between people, what was meant, what was felt, what was wanted, and what could be tried next. For many adolescents, that is the exact level at which change becomes possible.

## 13. Review and Discussion Questions

**Review and Discussion Questions**

1. Explain why interpersonal psychotherapy may be especially relevant during adolescence.
2. Distinguish grief, role disputes, role transitions, and interpersonal deficits, giving one adolescent example of each.
3. What are the risks of treating a school-based interpersonal problem as though it were caused only by the student's communication style?
4. Why is confidentiality more complex when parents participate in IPT-A?
5. Compare communication analysis with cognitive restructuring. What does each method notice?
6. In the case of Amara, why was expanding her social world as important as repairing one friendship?
7. When should IPT-A be combined with, or deferred in favour of, another intervention?

## 14. Practice Activities

**Practice and Application**

### Activity 41.1 — Interpersonal inventory

Construct a fictional interpersonal inventory for a sixteen-year-old whose parent has recently remarried. Identify one likely focus area and justify excluding the others for now.

### Activity 41.2 — Communication chain

Rewrite the statement “My mum never listens” as a six-step communication chain using observable words, tone, interpretation, feeling, response, and consequence.

### Activity 41.3 — Ethical decision

A parent asks for the content of every IPT-A session as a condition of continued transport to appointments. Write a response that preserves the therapeutic frame, explains safeguarding limits, and avoids shaming the parent.

## 15. Annotated Reading Pathways

**For the model.** Read Klerman and Weissman for the adult foundations, then Mufson's adolescent adaptation. The movement from adult IPT to IPT-A shows how a treatment changes when dependence, school, family authority, and peer belonging are placed at the centre.

**For evidence.** Read the school-based IPT-A trials and systematic reviews of adolescent depression treatments. Pay attention to comparison conditions: “usual care” in a well-resourced school is not the same intervention everywhere.

**For practice.** Study communication analysis transcripts. The skill lies less in naming a problem area than in slowing an exchange down until feeling, interpretation, and wish can be distinguished.

**For cultural adaptation.** Read work on family hierarchy, indirect communication, migration, faith communities, and collectivist decision-making. Then ask how each IPT-A technique would change without losing its interpersonal focus.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Interpersonal Psychotherapy for Adolescents** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is klerman's model, the social problem-solving curriculum, and the treatment of adolescent depression. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is safety, regulation, emotion, memory, relationships, and paced therapeutic work. The mechanism to keep in view is how threat, arousal, avoidance, meaning, and relational safety shape what a young person can feel, remember, and learn. The characteristic professional risk is moving into traumatic material before stabilisation, confusing calm with shutdown, or making disclosure the price of care. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 7. Apply the method | Use the chapter's core procedures in stabilisation sessions, trauma-informed schools and services, caregiver work, and specialist treatment pathways, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support,

timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Sofia is fifteen and is seen in a family support service for repeated classroom escalation. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Sofia's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Sofia explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on safety, regulation, emotion, memory, relationships, and paced therapeutic work. The first intervention is deliberately modest. Sofia chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Sofia has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Sofia can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be

sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Interpersonal Psychotherapy for Adolescents

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Interpersonal Psychotherapy for Adolescents** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

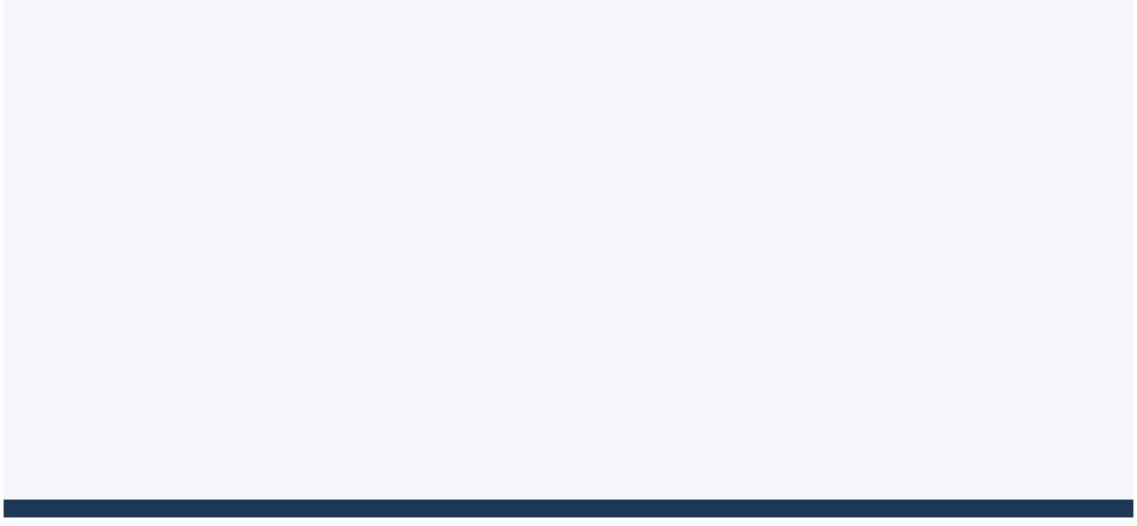
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Interpersonal Psychotherapy for Adolescents** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Interpersonal Psychotherapy for Adolescents**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into



clinical governance.

**Written consolidation.** In 250 words, explain Interpersonal Psychotherapy for Adolescents to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 42

# Mentalization-Based Treatment

Fonagy's model of mentalizing, the not-knowing stance, and epistemic trust.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Define mentalizing and distinguish reflective functioning from empathy, insight, theory of mind, and emotional intelligence.
- Explain how mentalizing develops in attachment relationships and why it becomes unstable under arousal.
- Describe psychic equivalence, pretend mode, and teleological mode.
- Explain epistemic trust and its relevance to therapeutic change.
- Describe the structure and stance of mentalization-based treatment for adolescents.
- Apply mentalizing interventions to misunderstandings, conflict, self-harm urges, and family interactions.
- Evaluate evidence, limitations, cultural questions, and ethical risks.

## Chapter Overview

Mentalizing is the capacity to understand behaviour—one's own and other people's—in terms of underlying mental states: feelings, beliefs, wishes, intentions, memories, and goals. It is the ordinary human activity by which a sigh is read as disappointment rather than tiredness, silence as embarrassment rather than hostility, and one's own sudden wish to leave a room as anxiety rather than proof that everyone present is dangerous.

Peter Fonagy and colleagues argue that this capacity is not simply inborn and then expressed. It develops within early relationships in which a caregiver notices, names, mirrors, and responds to the child's internal states in a way that is marked enough to be recognisable and contingent enough to be useful. The child gradually learns: this feeling is mine; it can be thought about; other people have minds too; their behaviour can be understood, though never known with certainty.

When attachment relationships are frightening, neglectful, chaotic, or invalidating, mentalizing may develop unevenly. Under stress it can collapse. A young person who can reflect thoughtfully when calm may, after a perceived rejection, become certain that a friend hates them, that a teacher is deliberately humiliating them, or that self-harm is the only action that will prove distress to adults. Mentalization-based treatment, or MBT, aims to restore the capacity to pause, notice mental states, consider alternatives, and recover curiosity—especially at the moments when curiosity disappears.

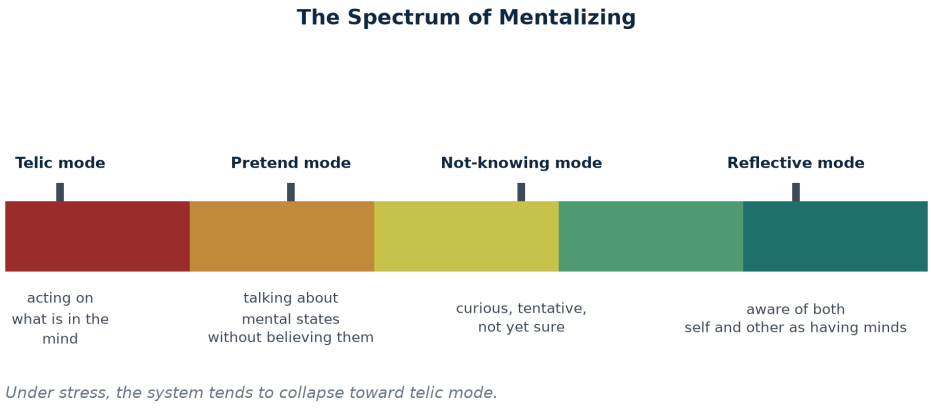


**Figure 42.29** The mentalizing spectrum, showing balanced mentalizing between automatic and controlled poles, and the collapse into psychic equivalence, pretend mode, and teleological mode under arousal.

## 1. Historical and Theoretical Context

Mentalization-based treatment emerged from psychoanalytic developmental research, attachment theory, and work with borderline personality disorder. Fonagy, Bateman, Target, and colleagues brought together several traditions: psychoanalytic interest in representation; developmental research on theory of mind; attachment research on reflective functioning; and clinical observation that people with severe personality difficulties often lose reflective capacity precisely when relationships matter most.

The model was later adapted for adolescents and families. MBT-A recognises that adolescent mentalizing is still developing. The prefrontal systems involved in controlled reflection are maturing; peer evaluation carries extraordinary salience; identity is unstable; and family relationships are being renegotiated. It would therefore be wrong to treat every adolescent failure to mentalize as pathology. Development itself involves oscillation between reflection and action, curiosity and certainty, dependence and defiance.

The clinical problem arises when collapse is frequent, prolonged, dangerous, or generalised: when misunderstandings reliably become crises, when intentions are assumed to be malicious, when feelings are experienced as facts, or when only visible action is trusted as proof of care.

## 2. What Mentalizing Is—and Is Not

Mentalizing overlaps with several familiar concepts but is not identical to any of them.

**Empathy** is primarily affective resonance and concern for another. A person may feel with someone yet misunderstand why they act.

**Theory of mind** usually refers to cognitive attribution of beliefs and intentions, often tested in developmental tasks. Mentalizing includes affect, self-experience, embodiment, and relationship context.

**Insight** implies knowledge about oneself, often verbal and retrospective. Mentalizing is a process used in real time, including when knowledge is incomplete.

**Emotional intelligence** is a broad popular and psychometric construct. Mentalizing is narrower and clinically observable: can this person, in this state, hold their own and another's perspective in mind?

**Mindfulness** involves attention to present experience. Mentalizing adds interpersonal interpretation: not only “I feel tense”, but “I feel tense because I expected criticism, and perhaps I misread her silence.”

Good mentalizing is not perfect mind reading. Indeed, excessive certainty is a failure of mentalizing. The mature position is sometimes called the **not-knowing stance**: mental states are opaque; interpretations are provisional; curiosity is preferable to premature conclusion.

# 3. Dimensions of Mentalizing

Mentalizing varies along four dimensions.

## 3.1 Automatic and controlled

Automatic mentalizing is rapid and intuitive: we sense irritation in a voice and soften our own. Controlled mentalizing is slower and reflective: we pause to ask what else could explain the behaviour. Health involves flexible movement between them. Under threat, controlled mentalizing often goes offline first.

## 3.2 Self and other

Some young people can explain everyone else's motives but have little access to their own feelings. Others are flooded by self-experience and cannot imagine the other person's position. Treatment identifies the imbalance rather than praising one side.

## 3.3 Internal and external

External mentalizing attends to facial expression, posture, tone, and behaviour. Internal mentalizing infers beliefs, wishes, and emotions. Trauma and neurodevelopmental differences may make external cues confusing; depression may make internal inference relentlessly negative.

## 3.4 Cognitive and affective

A young person may construct an intellectually elaborate account of a parent's motives while feeling nothing. Another may be overwhelmed by feeling with no narrative at all. Balanced mentalizing links thought and feeling without either dominating completely.

# 4. Attachment, Marked Mirroring, and Development

The developmental account begins with contingent mirroring. An infant expresses distress. The caregiver reflects an expression that resembles the infant's state but is marked—slightly exaggerated, softened, or framed by voice and facial cues—so that the infant can recognise it as a representation of their feeling rather than the caregiver's own overwhelming emotion.

Through repeated experiences, the child develops second-order representations: feelings become thinkable. A caregiver who is consistently frightening, absent, mocking, or overwhelmed cannot provide this reliably. The child may then experience feelings as alien, dangerous, or unrepresentable.

Adolescence offers a second developmental opportunity. Friends, teachers, mentors, romantic partners, and therapists can provide new experiences of being understood. But peer mirroring is volatile. Social media adds rapid, quantified, ambiguous feedback—likes, views, read receipts, screenshots—which can intensify mentalizing errors. A delayed reply is thin evidence, yet the adolescent mind may treat it as a verdict.

# 5. Failure Modes

## 5.1 Psychic equivalence

In psychic equivalence, internal experience is treated as external reality. “I feel rejected, therefore you rejected me.” “I am sure she is laughing at me, so she is.” There is no gap between thought and fact. Challenging the belief directly often increases defensiveness because the person experiences disagreement as denial of reality.

The intervention is not argument. It is slowing down: identifying the feeling, separating sequence from interpretation, and generating alternatives.

## 5.2 Pretend mode

In pretend mode, mental-state language becomes detached from lived reality. A young person may speak fluently about trauma, attachment, boundaries, and triggers while showing no affective connection and making no change. Therapy language itself can become pretend mode. Sessions feel sophisticated but weightless.

The intervention is to return to a concrete recent moment: What happened just before you said that? What did you notice in your body? What did you want the other person to do?

## 5.3 Teleological mode

In teleological mode, mental states are believed only when proved by visible action. “If you cared, you would answer immediately.” “If school understood, they would let me leave.” Words are discounted; only outcomes count. This mode often appears where words have repeatedly been unreliable.

The intervention validates the history behind the demand while gradually expanding what can count as evidence: consistency over time, repair after failure, and noticing intention as well as result.

## 5.4 Hypermentalizing and hypomentalizing

Hypermentalizing produces elaborate, overconfident interpretations from limited evidence. Hypomentalizing produces concrete, minimal, or absent reflection: “Dunno”, “She's just annoying”, “He did it for no reason.” Both can look like opposition. Both require pacing and curiosity rather than interpretation imposed from above.

# 6. Epistemic Trust

Epistemic trust is openness to learning from another person as a source of socially relevant knowledge. When a young person experiences a therapist as genuinely trying to understand their mind, they may become more able to consider new perspectives outside therapy. The mechanism is relational before it is

technical.

This has an important implication: MBT is not a bag of clever questions. If the practitioner is rushed, sarcastic, frightened, punitive, or mainly interested in compliance, mentalizing language will not create trust. The practitioner's own mentalizing is continuously on display, including how they handle mistakes.

When epistemic mistrust is high, the young person may treat all professional communication as manipulation. Consistency, transparency, repair, and practical reliability matter more than sophisticated formulation.

## 8. The Structure of MBT-A

MBT-A usually combines individual sessions, family or parent sessions, group work in some settings, crisis planning, and close team communication. The precise format varies, but several structural principles recur.

**Assessment of mentalizing.** The practitioner observes how the young person describes self and others when calm and when aroused. Useful questions include: When a friend does not reply, what explanations occur to you? When you are angry with your mother, can you imagine what she may be frightened of? When you cut, what do you hope adults will understand?

**Formulation in mentalizing terms.** Instead of listing only symptoms, the formulation identifies triggers for collapse, characteristic failure modes, relational patterns, strengths, and recovery routes. Example: “When Mia feels ignored, she moves quickly into psychic equivalence: not being answered means being hated. She then sends escalating messages. When replies become angry, the original fear appears confirmed. She recovers mentalizing when given time, written summaries, and one consistent adult who does not retaliate.”

**A shared crisis plan.** The plan states what helps when mentalizing is lost: pause contact, move to a safe place, contact a named adult, use grounding, delay irreversible messages, and agree when communication will resume. It should be written before crisis if possible.

**Team mentalizing.** Staff also lose mentalizing under pressure. Teams begin describing a young person as manipulative, attention-seeking, or dangerous in a totalising way. MBT therefore includes team reflection

on the team's own states. This is not indulgence; it is risk management.

## 9. The Therapist's Stance

The MBT stance is active, curious, humble, and affect-focused. The practitioner frequently says, in substance:

- “I may be getting this wrong.”
- “Can we slow that moment down?”
- “What went through your mind just before you walked out?”
- “What do you imagine was happening for him?”
- “What other explanation could there be, even if it does not feel likely right now?”
- “I notice I started sounding like I was telling you off. Let me try again.”

Questions are short. Long interpretations during high arousal usually fail. The practitioner tracks shifts moment by moment: voice, posture, eye contact, certainty, humour, silence. When mentalizing collapses, the work becomes support, validation, grounding, and clarification of immediate facts. Exploration resumes when arousal falls.

The practitioner also mentalizes themselves aloud in a disciplined way. “I realise I assumed you were angry with me because you went quiet. I might have misread tiredness.” This models fallibility without making the young person responsible for the therapist's feelings.

## 10. Core Interventions

### 10.1 Stop, rewind, explore

A recent interaction is paused at the point where misunderstanding accelerated. Each step is reconstructed: event, sensation, interpretation, feeling, impulse, action, other's likely interpretation. The aim is not to assign blame but to recover sequence.

### 10.2 Mentalizing the moment

The practitioner notices a shift in the session itself. “When I looked at the clock, you went quiet. What did you make of that?” The therapy relationship becomes a live laboratory, provided the practitioner does not make every exchange about transference or pressure the young person to disclose more than is safe.

### 10.3 Affect identification and elaboration

Vague arousal is differentiated: irritation, shame, fear, loneliness, jealousy, guilt, disgust, grief. Naming does not magically regulate, but it creates a gap between impulse and action.

### 10.4 Challenge and support

MBT balances support with gentle challenge. Excess support can maintain avoidance; excessive challenge causes collapse. A useful intervention is: “I understand why sending that message felt urgent. Can we also think about what she may have read in it?”

### 10.5 Countertransference and practitioner repair

If the practitioner becomes bored, frightened, angry, rescuing, or punitive, that response is information but not instruction. Supervision helps distinguish the young person's interpersonal pull from the practitioner's history and the service's pressures. When the practitioner makes an error, repair is itself treatment.

## 11. Family Work

Families often arrive with competing certainties. A parent is certain a slammed door means contempt; the adolescent is certain a question means surveillance. Family MBT slows exchanges and asks each person to state feelings and intentions while the other listens without immediate rebuttal.

Parents are helped to distinguish behaviour from inferred motive. “He slammed the door” is observable. “He has no respect” is interpretation. The adolescent is similarly helped to distinguish a parent's anxious checking from proof of hatred or control, while the parent is still required to change behaviour that is intrusive or unsafe. Mentalizing never means the less powerful person must endlessly excuse harmful conduct.

Family sessions require ground rules: one speaker at a time, no diagnosing one another, pause when arousal rises, and a return to a concrete recent example. Where coercive control, violence, or sexual abuse is present, conjoint mentalizing work may be unsafe. Separate work and safeguarding come first.

## 12. Case Illustration: “If You Cared, You'd Answer”

**Presentation.** Lea is sixteen and has been referred after repeated self-harm following friendship conflicts. She describes intense attachments that shift quickly from idealisation to certainty of betrayal. After a friend failed to answer messages during a family meal, Lea sent twenty-seven messages, then cut her arm and sent a photograph to another friend “so somebody would actually get it”.

**Mentalizing formulation.** When calm, Lea is perceptive and funny. Perceived delay triggers abandonment fear. She enters psychic equivalence: the feeling of being ignored becomes proof of deliberate rejection. She then shifts to teleological mode: only immediate reply or visible crisis counts as care. Afterward she feels shame and concludes she is “too much”, which increases future vigilance.

**Treatment.** The therapist and Lea construct a pause plan. When she notices the urge to send a third message, she writes the unsent message in a notes application, uses cold water and paced breathing, and waits twenty minutes before deciding. She and her closest friend, with consent, discuss a realistic reply norm during school and family meals. This is not the friend becoming a clinician; it is reducing ambiguity that fuels collapse.

In session, the therapist repeatedly uses stop–rewind–explore. One exchange is slowed down second by second. Lea notices that the first thought was not “she hates me” but “I feel stupid for caring”. Shame precedes accusation. That recognition matters because the intervention changes: the task becomes tolerating shame without converting it into proof of rejection.

Her mother joins selected sessions. She learns to say, “I can see this feels urgent. I am not going anywhere, but I need us to pause before we shout,” rather than either confiscating the phone immediately or promising constant availability. Lea learns to say, “I need reassurance” before escalating.

After nine months, Lea still experiences intense jealousy and abandonment fears, but episodes are shorter, self-harm has reduced, and she can often say, “I feel dropped; I don't actually know that I am.” That sentence is not cosmetic. It marks the recovery of a gap between feeling and fact.

## 13. Evidence and Research Support

The strongest adolescent evidence is the randomised trial by Rossouw and Fonagy (2012), in which MBT-A for adolescents who self-harm produced greater reductions in self-harm and depression than usual care, with improvement in mentalizing and attachment-related measures proposed as mechanisms. Adult MBT has a substantial evidence base for borderline personality disorder, including longer-term follow-up studies.

Evidence remains less extensive than for some cognitive-behavioural treatments. Studies are relatively small; implementation requires training; comparison treatments vary; and adolescent services often adapt the model. MBT should therefore be presented as evidence-supported and promising, not as a universal answer to adolescent distress.

MBT is particularly relevant where self-harm, emotional instability, interpersonal sensitivity, attachment disruption, and repeated relational crises dominate. It is not a stand-alone treatment for psychosis, mania, severe eating disorders, substance dependence, obsessive-compulsive disorder, or acute safeguarding danger, though mentalizing principles may inform wider care.

## 14. Strengths and Limitations

Strengths include a coherent developmental theory, attention to therapeutic relationship and team states, usefulness in relational crises, and a respectful not-knowing stance. It helps practitioners understand why reasoning fails under arousal and why consistency and repair matter.

Limitations include training demands, risk of jargon, dependence on verbal reflection, and the danger of interpreting behaviour while neglecting material conditions. A hungry, unsafe, bullied, or sleep-deprived adolescent does not primarily need more sophisticated reflection. Mentalizing must sit alongside safeguarding, practical help, medical care, education advocacy, and family support.

## 15. Cultural and Ethical Considerations

Cultures differ in directness, emotional display, family hierarchy, privacy, and explanations of behaviour—including spiritual, moral, biomedical, and social explanations. The practitioner should not treat Western psychological mindedness as the sole mature form. A young person may mentalize through story, proverb, humour, silence, prayer-free communal reflection, art, music, or action rather than explicit “I think you feel” language; the task is to recognise reflective capacity in culturally available forms, without introducing religious content where the client has not chosen it.

Ethically, mentalizing must not become a sophisticated way to blame the young person for adult failures. If a parent is violent, a school discriminatory, or a placement unstable, the correct intervention may be protection and system change. Consent, assent, confidentiality, and the right not to disclose remain essential. Group work requires explicit rules about privacy and digital recording. Practitioners should avoid labelling adolescents with personality disorder language casually; developmental instability is not destiny.

## 16. Key Terms

**Key Terms at a Glance**

- **Mentalizing** — Understanding behaviour in terms of mental states such as feelings, beliefs, wishes, and intentions.
- **Reflective functioning** — The measurable capacity to reflect on mental states in oneself and others.
- **Psychic equivalence** — Treating an internal feeling or belief as external fact.
- **Pretend mode** — Mental-state talk disconnected from affect and real experience.
- **Teleological mode** — Accepting only visible action as proof of intention or care.
- **Epistemic trust** — Openness to learning from another person perceived as trustworthy and genuinely interested in one's mind.
- **Marked mirroring** — Caregiver reflection of a child's state in a form recognisable as representation rather than the caregiver's own raw emotion.
- **Not-knowing stance** — Curious acknowledgement that mental states cannot be known with certainty.

## 17. Chapter Summary

Mentalization-based treatment begins from a simple observation: when arousal rises, people lose the ability to think about minds. Adolescents may then act on feelings as facts, demand visible proof of care, or produce fluent psychological language that touches nothing. Treatment restores curiosity through a reliable relationship, slow reconstruction of interactions, affect naming, family work, crisis planning, and practitioner repair.

The model is at its best when it creates a pause—the small but decisive space in which a young person can say: this is what I feel, this is what I inferred, this is what else might be true, and this is what I will do next.

## 18. Review and Discussion Questions

**Review and Discussion Questions**

1. Distinguish mentalizing from empathy and theory of mind.
2. Give adolescent examples of psychic equivalence, pretend mode, and teleological mode.
3. Why does direct argument usually fail when psychic equivalence is active?
4. Explain epistemic trust in ordinary clinical language.
5. How can a practitioner's repair of their own mistake become therapeutic?
6. What must be addressed before family mentalizing work is safe?
7. Evaluate the evidence for MBT-A and identify two limitations.

## 19. Practice Activities

**Practice and Application**

### Activity 42.1 — Stop, rewind, explore

Take a fictional two-minute argument between a parent and adolescent. Write the trigger, sensation, interpretation, feeling, impulse, action, and likely interpretation by the other person.

### Activity 42.2 — Three explanations

A friend does not reply for five hours. Generate explanations from psychic equivalence, hypermentalizing, and balanced mentalizing.

### Activity 42.3 — Practitioner repair

Write a brief repair statement for a counsellor who incorrectly assumed a quiet adolescent was angry and became defensive.

## 20. Annotated Reading Pathways

**For theory.** Fonagy and colleagues' developmental work remains foundational. Read it alongside attachment research rather than as a replacement for it.

**For practice.** Bateman and Fonagy's practical guide and Asen and Fonagy's family work show how the stance becomes interventions.

**For evidence.** Begin with Rossouw and Fonagy's adolescent self-harm trial, then examine later implementation studies and systematic reviews with attention to sample size and comparison care.

**For critique.** Read cultural and neurodiversity-informed critiques of reflective functioning measures. Ask whose communication style the instrument treats as standard.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Mentalization-Based Treatment** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is fonagy's model of mentalizing, the not-knowing stance, and epistemic trust. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is safety, regulation, emotion, memory, relationships, and paced therapeutic work. The mechanism to keep in view is how threat, arousal, avoidance, meaning, and relational safety shape what a young person can feel, remember, and learn. The characteristic professional risk is moving into traumatic material before stabilisation, confusing calm with shutdown, or making disclosure the price of care. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

## A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in stabilisation sessions, trauma-informed schools and services, caregiver work, and specialist treatment pathways, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and**

**eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Daniel is fifteen and is seen in an integrated school and health team for difficulty trusting adults after several service changes. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Daniel's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Daniel explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on safety, regulation, emotion, memory, relationships, and paced therapeutic work. The first intervention is deliberately modest. Daniel chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Daniel has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Daniel can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Mentalization-Based Treatment

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Mentalization-Based Treatment** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

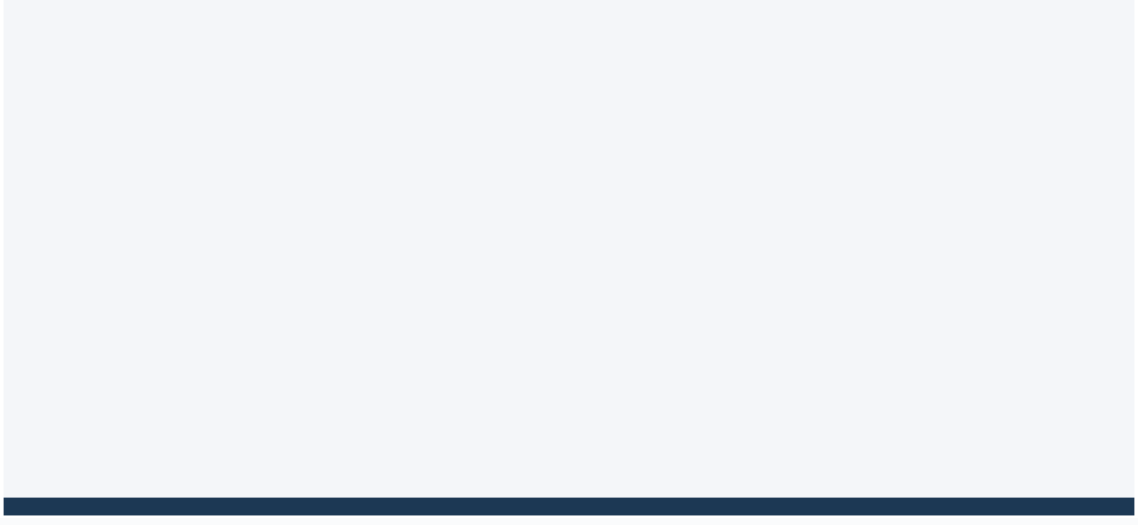
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Mentalization-Based Treatment** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Mentalization-Based Treatment**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.



**Written consolidation.** In 250 words, explain Mentalization-Based Treatment to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the

listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 43

# Somatic, Sensorimotor, and Polyvagal-Informed Practice

Body-based approaches, autonomic regulation, and the neuroception of safety.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain why trauma, anxiety, and chronic stress may be expressed through the body.
- Describe autonomic states using polyvagal-informed language while recognising scientific debate about aspects of polyvagal theory.
- Explain the window of tolerance and identify hyperarousal, hypoarousal, and regulated engagement.
- Describe sensorimotor and somatic assessment: posture, breath, movement, sensation, impulse, and procedural patterns.
- Use grounding, orienting, breathing, movement, and boundary exercises safely.
- Distinguish somatic work from massage, physical therapy, medical treatment, and touch-based interventions requiring separate consent and competence.
- Apply somatic principles to adolescents with trauma, panic, dissociation, chronic pain presentations, and shutdown.
- Evaluate evidence, cultural considerations, safeguarding, and ethical limits.

## Chapter Overview

Some young people can describe events but not feelings. Some can recite coping strategies while their shoulders rise, breathing quickens, hands shake, or gaze becomes fixed. Others become inexplicably sleepy, blank, compliant, or absent when a subject approaches danger. Somatic and sensorimotor approaches begin with these observations: psychological life is embodied, and regulation is not achieved by instruction alone.

The word *somatic* refers to the lived body. *Sensorimotor* emphasises sensation and movement: what the body senses, prepares to do, inhibits, or repeats. Polyvagal-informed practice draws on Stephen Porges' account of autonomic regulation and social engagement, while responsible teaching must acknowledge that some specific anatomical and evolutionary claims of polyvagal theory are contested. Clinicians can use the practical language of safety, mobilisation, shutdown, and co-regulation without presenting every theoretical claim as settled neuroscience.

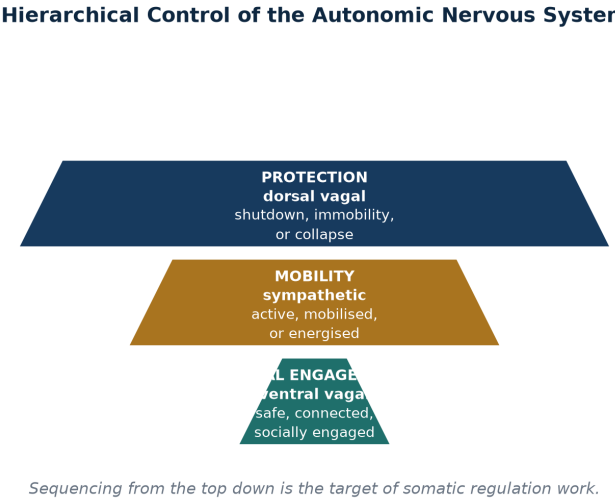


**Figure 43.30** The autonomic hierarchy, showing social engagement, mobilisation, and shutdown states, with cues of safety and danger influencing movement between them.

## 1. Why the Body Matters

Threat prepares action. Muscles tense, breathing changes, digestion slows, attention narrows, and the body prepares to fight, flee, freeze, submit, or seek help. When threat passes, a regulated system can complete the arousal cycle and return to rest, appetite, play, learning, and social connection.

When threat is chronic, unpredictable, or inescapable, adaptive responses may become habitual. A student may scan every classroom for exits, startle at a door, hold their breath when criticised, collapse into exhaustion after school, or experience stomach pain before separation. These are not character defects. They may be procedural learning: the body has learned what to do before conscious appraisal catches up.

Talk remains important, but talk delivered to a body in alarm may be heard as noise or threat. The practitioner's voice, pace, facial expression, distance, posture, and predictability are therefore clinical variables, not decorative bedside manner.

## 2. Autonomic States in Clinical Language

A simplified three-state map is useful for teaching.

**Social engagement and relative safety.** Breathing is flexible; voice has prosody; facial muscles move; eye contact can be chosen; digestion and rest are possible; curiosity returns. The young person can listen, disagree, joke, and learn.

**Mobilisation.** Sympathetic arousal supports fight or flight. The young person may be restless, irritable, argumentative, panicky, vigilant, unable to sit still, or desperate to leave. The clinical need is not immediate insight but reduction of danger cues and safe discharge or settling of energy.

**Shutdown or immobilisation.** The young person may become quiet, numb, slowed, blank, dissociated, overly compliant, or unable to speak. Adults often misread this as calm or defiance. The clinical need is

gentle orientation, choice, movement, sensory input, and connection without demand.

These states are not moral ranks and not diagnoses. A person moves among them. Shutdown may be life-preserving during unavoidable threat. Mobilisation may be appropriate in sport or emergency. Problems arise when transitions are rigid, prolonged, or triggered by cues that no longer signal actual danger.

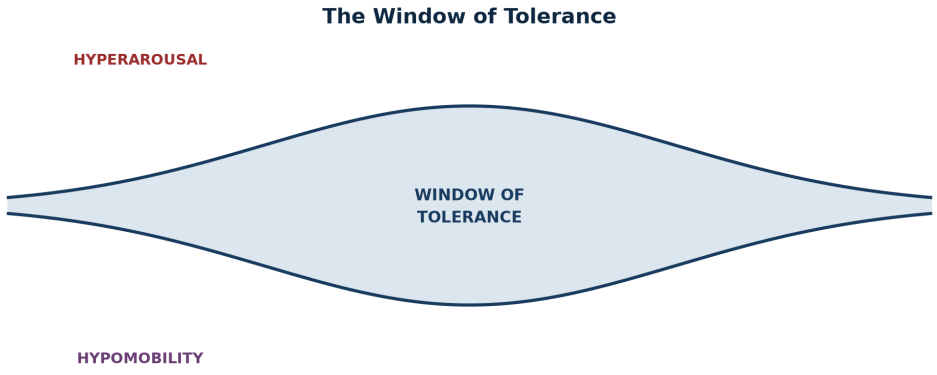

**Figure 43.31** The window of tolerance, showing regulated arousal between hyperarousal and hypoarousal, and the widening of the window through safety, skills, and co-regulation.

## 3. The Window of Tolerance

Daniel Siegel popularised the window of tolerance as the arousal band within which a person can process emotion and information without becoming overwhelmed or shutting down. Trauma, sleep deprivation, pain, hunger, illness, sensory overload, and ongoing danger narrow the window. Safety, rhythm, predictability, relationships, movement, rest, and skills widen it.

Assessment therefore asks: What narrows this young person's window? What are the first signs of leaving it? What helps return? Who helps? Which environments make regulation easier? What does the young person already do—music, walking, drawing, sport, humour, prayer-free private reflection, being with animals, coding, cooking—that genuinely settles the body rather than merely distracting adults?

## 4. Sensorimotor Assessment

Assessment is observational and collaborative. The practitioner notices, without over-interpreting:

- posture: collapsed, braced, twisted away, frozen, restless;
- breath: shallow, held, rapid, sighing, mainly upper chest;
- movement: fidgeting, rocking, leg shaking, immobility, repeated gestures;
- voice: monotone, rushed, whispering, unusually loud;
- gaze and facial expression;
- reported sensation: pressure, heat, nausea, tingling, pain, emptiness;
- action impulses: urge to run, hide, hit, curl up, shout, cry, laugh, or disappear.

Questions are concrete: “As you mention the classroom, what changes in your body?” “Where does the tightness begin?” “Does your body want to move closer, back away, or become very still?” The young person may answer with metaphor—“a knot”, “static”, “a wall”—and the metaphor should be respected rather than translated too quickly.

Medical assessment matters. Pain, thyroid disease, anaemia, asthma, cardiac symptoms, medication effects, substance use, seizures, sleep apnoea, and many other conditions can mimic or amplify anxiety and dissociation. Somatic practice never replaces medical evaluation.

## 5. Principles of Intervention

**Safety and choice.** The young person controls pace, may keep eyes open, may decline an exercise, and knows they can stop. Choice is regulating.

**Titration.** Work occurs in small doses. Attention moves between a difficult sensation and a resource—a stable chair, a pleasant image, a steady breath—rather than flooding the system.

**Pendulation.** The practitioner helps the young person move attention between activation and settling, building confidence that states can change.

**Completion and discharge.** After mobilisation, the body may need walking, shaking out limbs, stretching, drinking water, or rest. The goal is not dramatic catharsis.

**Co-regulation before self-regulation.** A calm adult, predictable routine, and relational repair precede expectations that the young person regulate alone.

**Meaning follows regulation.** Narrative linking—“this stomach tightening happens when you expect criticism”—is more useful after the sensation can be noticed without overwhelm.

## 7. Core Practices

### 7.1 Orienting

Orienting uses sight, hearing, and proprioception to establish present safety. The young person slowly looks around, names colours or objects, notices support from the chair and floor, and identifies exits without rehearsing escape. The exercise must be adapted where the current environment is genuinely unsafe;

pretending safety is not treatment.

### 7.2 Grounding

Grounding anchors attention in present sensory information: feet on the floor, back against a chair, holding a textured object, listening for near and far sounds, splashing cold water, or naming five observable details. Grounding is not a command to “calm down”. It is an invitation to collect evidence of here and now.

### 7.3 Breath

Slow breathing with a comfortable extended exhale can reduce arousal for some people. Breath work can also provoke panic, traumatic memories, dizziness, or a sense of control. Alternatives include breathing through movement, humming, singing, walking rhythm, or simply noticing natural breath. No adolescent should be forced to close their eyes or breathe in a prescribed pattern.

### 7.4 Movement and posture

Small experiments are preferable to dramatic release. Press feet into the floor. Push palms together. Stand and feel balance. Uncurl slowly from a collapsed posture. Walk the corridor. Shake hands and shoulders. Notice whether energy, breath, or emotion changes. The practitioner asks, “What is different?” rather than announcing what should be felt.

### 7.5 Boundaries in the body

Boundary work may involve noticing comfortable distance, practising saying “stop”, imagining a protective space, choosing where to sit, or using gesture to mark “enough”. For adolescents whose boundaries have been violated, bodily choice is therapeutic content, not a preliminary courtesy.

### 7.6 Tracking sensation and impulse

The practitioner helps sequence experience: sensation, emotion, impulse, thought, action. “My chest tightens; I feel trapped; I want to run; I think she'll shout; I leave.” Once sequence is visible, intervention points multiply. The young person might move, ask for a pause, clarify the other's intention, or choose a safer exit—not merely suppress leaving.

## 8. Somatic Work with Adolescents

Adolescents may find body-focused work embarrassing, especially amid puberty, body image concerns, disability, chronic illness, gender dysphoria, cultural modesty, or previous medical trauma. Language should be neutral and permission-based. Mirrors, touch, close physical proximity, and comments about appearance are avoided unless clinically essential, separately justified, consented, and within professional scope.

Sport, dance, martial arts, drama, music, outdoor activity, and occupational therapy may provide regulating experiences, but adults should not label every enjoyable activity “therapy” or remove its intrinsic value by over-clinicalising it. Sometimes the best somatic intervention is helping a young person safely return to football, swimming, drumming, or walking a dog.

Sleep is a somatic intervention. So are regular meals, treatment of pain, reduced late-night caffeine and energy drinks, management of sensory overload, and a school timetable that does not demand constant vigilance. A counsellor who ignores these basics while teaching sophisticated nervous-system language has reversed the clinical order.

## 9. Case Illustration: The Student Who Went Blank

**Presentation.** Tomas, fourteen, is repeatedly sanctioned for ignoring teachers. During conflict he stares, stops answering, and later cannot recall instructions. Staff interpret this as selective defiance. At home he becomes loud and restless after school, then sleeps for hours.

**Assessment.** The counsellor notices that when a male teacher raises his voice in a role-played example, Tomas' shoulders rise, breathing stops briefly, gaze fixes, and his hands become still. Tomas reports “everything goes fuzzy”. He denies choosing not to answer: “I can hear, but words don't come.” There is a history of witnessing severe domestic conflict before age nine. Medical screening and hearing assessment are arranged to avoid assuming a trauma explanation.

**Formulation.** Tomas oscillates between mobilisation and shutdown. Raised voices and public correction rapidly narrow his window. Stillness is a protective hypoarousal response, not evidence of calm. After school, accumulated arousal discharges through restlessness, followed by exhaustion.

**Intervention.** Work begins without trauma narration. Tomas maps early signs: ears “buzz”, jaw tightens, thoughts slow. He chooses signals with teachers: a break card, a seat near the door, and permission to stand at the back for two minutes rather than leaving unsupervised. Staff are coached—through proper consent and school consultation—to lower voice volume, give one instruction at a time, and check understanding after he has settled.

In counselling, Tomas practises orienting with eyes open, pressing feet into the floor, slow walking, and extending exhale only when it feels comfortable. He dislikes body scans because attention to his chest increases panic; that preference is respected. He learns to say, “I need a minute; I'm not refusing.” Teachers learn to hear that sentence as the beginning of regulation, not a challenge.

His mother is helped to create an after-school decompression routine: food, thirty minutes without questioning, physical activity, then homework in two short blocks. The counsellor does not ask Tomas to recount violent incidents. Later, when stability improves, he chooses to discuss one memory in a trauma-focused treatment with a trained clinician.

**Outcome.** Sanctions decrease. Tomas still becomes blank occasionally, but he recognises early signs and uses the break card before shutdown. The central change is interpretive as well as physiological: adults stop treating stillness as proof of contempt, and Tomas stops treating his body as evidence that he is “broken”.

## 10. Evidence and Critical Evaluation

Evidence for body-oriented trauma therapies is promising but uneven. Sensorimotor psychotherapy, somatic experiencing, trauma-sensitive yoga, breath and movement interventions, and related approaches have supportive studies, but many trials are small, heterogeneous, and difficult to blind. Outcomes may reflect therapeutic relationship, expectancy, exercise, sleep improvement, and general support as well as specific mechanisms.

Polyvagal theory has been clinically influential, especially in translating safety and co-regulation into practice. However, scholars dispute aspects of its evolutionary sequence, vagal measurement, and interpretation of respiratory sinus arrhythmia. Ethical teaching therefore distinguishes between: well-supported observations that safety cues and relationships affect arousal; plausible clinical heuristics about states; and contested neuroanatomical claims. Students should be suspicious of any programme that claims a proprietary exercise can diagnose trauma from heart-rate patterns or “reset” a nervous system in one session.

## 11. Ethics, Touch, and Safeguarding

Touch requires exceptional care with minors. Default practice in counselling should be no therapeutic touch unless there is a clear rationale, professional training, organisational policy, informed parental consent where required, the young person's ongoing assent, a chaperone or visibility where appropriate, and immediate respect for withdrawal. Many somatic interventions require no touch at all.

The practitioner must avoid suggesting that bodily responses prove a particular history. A startle response does not prove abuse; pelvic pain does not prove sexual trauma; dissociation has multiple causes. Somatic work must not become a memory-recovery technique. If disclosures occur, safeguarding procedures govern the response.

Cultural practices around modesty, gender, disability, movement, eye contact, and bodily display vary. Ask what is acceptable. Offer alternatives. Never require removing clothing, being filmed, closing eyes, or physical contact as proof of engagement.

## 12. Key Terms

**Key Terms at a Glance**

- **Somatic** — Relating to lived bodily experience.
- **Sensorimotor** — Linking sensation, posture, movement, and action impulses.
- **Co-regulation** — Regulation supported through a safe relationship.
- **Titration** — Working with activation in small, manageable doses.
- **Pendulation** — Moving attention between distress and resource to build flexibility.
- **Window of tolerance** — The arousal range in which processing and learning remain possible.
- **Orienting** — Using sensory attention to establish present-time safety.
- **Procedural learning** — Bodily patterns learned through repetition rather than conscious declaration.

## 13. Chapter Summary

Somatic and sensorimotor practice teaches counsellors to notice the body without worshipping or over-interpreting it. Breath, posture, sensation, movement, sleep, pain, and relational safety provide

information and points of intervention. Used humbly, these approaches help young people recognise state changes, widen their window of tolerance, and recover choice before, during, and after talk-based work.

## 14. Review and Discussion Questions

**Review and Discussion Questions**

1. Distinguish mobilisation, social engagement, and shutdown in observable terms.
2. Why can a quiet adolescent be more dysregulated than a noisy one?
3. Give three alternatives when breath-focused work increases panic.
4. Why is choice itself a regulating intervention?
5. Which claims of polyvagal-informed practice should be taught cautiously?
6. Write a no-touch somatic plan for a student who dissociates during conflict.
7. When should medical assessment take priority over somatic formulation?

## 15. Practice Activities

**Practice and Application**

### Activity 43.1 — State map

Create a personal state map: early bodily signs, thoughts, impulses, helpful people, places, movements, and sensory resources for hyperarousal and hypoarousal.

### Activity 43.2 — Micro-experiment

Practise orienting with eyes open for ninety seconds. Record changes without claiming that the exercise must work for everyone.

### Activity 43.3 — School consultation

Draft guidance for teachers on responding to a student who becomes blank and silent during confrontation.

## 16. Annotated Reading Pathways

**For foundations.** Begin with Ogden's sensorimotor work and Dana's clinically accessible polyvagal translation.

**For critique.** Read scientific critiques of polyvagal theory alongside Porges, so that clinical usefulness does not become uncritical certainty.

**For adolescents.** Combine somatic reading with developmental neuroscience, sleep medicine, pain assessment, and trauma-informed school practice.

**For ethics.** Study professional guidance on touch, consent, physical interventions, and work with minors before using body-based methods.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Somatic, Sensorimotor, and Polyvagal-Informed Practice** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is body-based approaches, autonomic regulation, and the neuroception of safety. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is safety, regulation, emotion, memory, relationships, and paced therapeutic work. The mechanism to keep in view is how threat, arousal, avoidance, meaning, and relational safety shape what a young person can feel, remember, and learn. The characteristic professional risk is moving into traumatic material before stabilisation, confusing calm with shutdown, or making disclosure the price of care. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 7. Apply the method | Use the chapter's core procedures in stabilisation sessions, trauma-informed schools and services, caregiver work, and specialist treatment pathways, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support,

timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Nia is fifteen and is seen in a school counselling service for low mood and withdrawal from friends. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Nia's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Nia explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on safety, regulation, emotion, memory, relationships, and paced therapeutic work. The first intervention is deliberately modest. Nia chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Nia has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Nia can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be

sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Somatic, Sensorimotor, and Polyvagal-Informed Practice

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Somatic, Sensorimotor, and Polyvagal-Informed Practice** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Somatic, Sensorimotor, and Polyvagal-Informed Practice** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Somatic, Sensorimotor, and Polyvagal-Informed Practice**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a

discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Somatic, Sensorimotor, and Polyvagal-Informed Practice to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

PART VII

# Motivational, Social, Developmental, and Cultural Theories

Theories that attend to motivation, to social learning, to development, and to the cultural and gendered location of the person in the world.

CHAPTER 44

# Motivational Interviewing

Miller and Rollnick's four processes, change talk, and the adolescent adaptation of a conversational method.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain ambivalence and why direct persuasion often strengthens resistance.
- Describe the spirit of motivational interviewing: partnership, acceptance, compassion, and empowerment.
- Use open questions, affirmations, reflective listening, and summaries with adolescents.
- Elicit and strengthen change talk while softening sustain talk without arguing.
- Describe engaging, focusing, evoking, and planning processes.
- Apply motivational interviewing to school attendance, substance use, health behaviour, family conflict, and treatment engagement.
- Recognise ethical limits, especially with mandated and minor clients.

## Chapter Overview

Motivational interviewing (MI), developed by William R. Miller and Stephen Rollnick, is a collaborative conversation style for strengthening a person's own motivation and commitment to change. Its central insight is that ambivalence is normal. An adolescent may want to stop vaping because breathing and sport matter, and want to continue because vaping regulates stress and maintains belonging. A student may want qualifications and also want to avoid classrooms where failure feels public. A parent may want a calmer home and fear that reducing control means losing authority.

When practitioners argue for change, ambivalent people often argue back—not because they are irrational, but because conversation assigns positions. If the counsellor takes the “you must change” side, the young person may defend freedom, pleasure, identity, or scepticism. MI reverses the arrangement: the practitioner evokes the young person's own reasons, values, hopes, and confidence, then supports autonomy in deciding what to do.

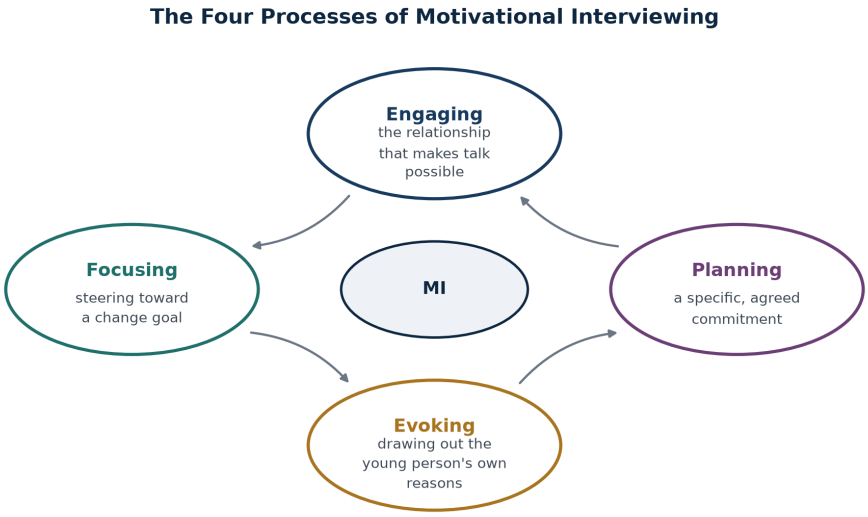

**Figure 44.32** The four processes of motivational interviewing: engaging, focusing, evoking, and planning, shown as a recursive cycle rather than a rigid staircase.

## 1. Development and Core Assumptions

MI emerged from addiction treatment in the 1980s, where Miller noticed that counsellor empathy predicted outcomes and that confrontational approaches often increased resistance. With Rollnick, the approach expanded into health care, corrections, education, parenting, and psychotherapy integration.

Four assumptions guide practice:

1. **Motivation is interpersonal.** It rises or falls within conversation.
2. **Ambivalence is not denial.** Mixed feelings contain useful information.
3. **People persuade themselves.** Statements spoken by the client—desire, ability, reasons, need, commitment—carry particular force.
4. **Autonomy is essential.** Change imposed without ownership is fragile and may be ethically unacceptable.

MI is not trickery to make a young person choose the adult's preferred outcome while feeling that it was their idea. That would violate its spirit. Transparency matters: the counsellor may state a concern, provide information with permission, and still respect the person's decision.

## 2. The Spirit of MI

Contemporary descriptions emphasise **partnership, acceptance, compassion, and empowerment**.

Partnership means working with, not on, the young person. Acceptance includes absolute worth, accurate empathy, autonomy support, and affirmation. Compassion places the young person's welfare above institutional convenience. Empowerment recognises existing strengths and resources rather than treating the client as empty until professionally filled.

The opposite spirit appears when the practitioner interrogates, labels, threatens, shames, or rushes to fix. Miller and Rollnick call the premature urge to solve the **fixing reflex**. With adolescents, the fixing reflex is amplified by adult responsibility: safeguarding, school targets, parental anxiety, and court or service mandates. MI does not remove those responsibilities; it changes how they are carried.

## 3. Change Talk and Sustain Talk

**Change talk** expresses movement toward change. Preparatory forms include desire (“I want”), ability (“I could”), reasons (“It would help”), and need (“I have to”). Mobilising forms include commitment (“I will”), activation (“I'm ready”), and taking steps (“I already tried”).

**Sustain talk** expresses movement away from change: pleasure, identity, fear, mistrust, practical barriers, loyalty to peers, or doubt. Sustain talk should not be crushed. It should be understood, reflected, and sometimes strategically explored so the young person can hear their own fuller position.

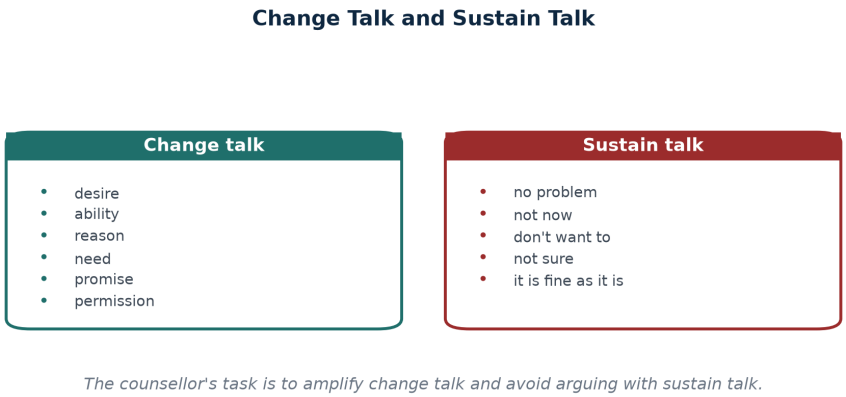

**Figure 44.33** Change talk and sustain talk as two sides of ambivalence, with counsellor reflections influencing which side becomes more elaborated.

A useful rule is that the more a young person argues for the status quo in session, the less likely change becomes. The counsellor therefore avoids supplying arguments that force the client into defence. Reflections often do more than questions because they allow the client to hear and revise their own meaning.

## 4. Core Skills: OARS

**Open questions** invite elaboration: “What concerns you most about how things are going?”

**Affirmations** recognise strengths and effort specifically: “You kept coming to appointments even though you expected to be lectured.”

**Reflective listening** forms the engine. Simple reflections repeat or slightly rephrase. Complex reflections add feeling, meaning, values, or the unstated side of ambivalence. A parent says, “He just doesn't care.” A reflection might be: “It's frightening to imagine he doesn't care, because then you feel powerless to reach him.” The aim is hypothesis, offered tentatively, not mind reading.

**Summaries** gather bouquets of change talk and offer them back: “You want your lungs back for football, you're tired of hiding devices from your mum, and you think weekdays might be easier than weekends. Did I miss anything?”

Advice is not forbidden. It is offered using elicit–provide–elicit: ask what the person knows and wants to know; offer information neutrally and with permission where required; elicit their interpretation and next step.

## 5. The Four Processes

**Engaging** establishes a working relationship. With adolescents, engagement includes explaining confidentiality, asking what would make sessions useful or unbearable, and noticing power differences.

**Focusing** identifies a direction. Several concerns may compete: attendance, cannabis, sleep, conflict, self-harm. Agenda mapping allows choice without pretending all can be solved at once.

**Evoking** draws out the young person's motivations, values, discrepancy, hopes, and confidence. This is the distinctive heart of MI.

**Planning** begins when motivation and confidence are sufficient. The practitioner supports a specific, chosen, realistic plan, anticipates barriers, and strengthens commitment without stealing ownership.

The processes are recursive. If planning produces resistance, return to evoking. If focus is unclear, return to engaging. Movement is not failure; it is information.

## 7. Working with Adolescent Ambivalence

Adolescents are developing autonomy under conditions of continued dependence. Adults control money, transport, school access, health care, privacy, and legal status. An invitation to “choose” may therefore be experienced sceptically. The counsellor should be explicit about what is negotiable and what is not.

Safety requirements are not preferences to be evoked away. If a young person is at serious risk, the practitioner acts protectively, explains why, and preserves as much choice as possible inside the safety frame: who is told first, where a conversation happens, which trusted adult is present, and what the young person wants recorded.

Mandated clients require honesty. A school may require attendance at a programme; a court may require treatment; a parent may require counselling. MI distinguishes the mandated frame from the young person's goals within it. “You didn't choose to be referred. Given that you're here, what—if anything—would make this time useful to you?” This respects reality without pretending coercion is consent.

# 8. Key Techniques

## 8.1 Importance and confidence rulers

“On a scale from 0 to 10, how important is improving attendance?” Then ask why the number is not lower, which evokes strengths and reasons, and what would move it one point higher. Confidence rulers follow the same pattern. Avoid asking first why the number is not higher; that invites barriers and defence.

## 8.2 Looking back and looking forward

Looking back recalls life before the problem or previous successes. Looking forward imagines a preferred future and its practical details. These are not fantasies; they generate discrepancy between values and current trajectory.

## 8.3 Exploring values

Sport, loyalty, freedom, competence, family respect, creativity, faith-neutral personal commitments, independence, and being trusted often matter more than abstract health warnings. The counsellor listens for values without exploiting them manipulatively.

## 8.4 Double-sided reflections

“You want your mum off your back, and you also hate lying because it makes you feel trapped.” A double-sided reflection holds both sides and often ends with change talk so the young person can respond to it.

## 8.5 Emphasising autonomy

“It really is your decision” is powerful only when true within the stated frame. Used falsely, it becomes coercion with softer language.

# 9. Case Illustration: “I'm Not Bothered About School”

**Presentation.** Malik, fifteen, attends school two days a week. Staff describe him as capable but unmotivated. His mother wants the counsellor to “make him understand” that examinations determine his future.

**Engaging.** The counsellor begins: “You didn't choose this referral. What would make these meetings not a waste of your time?” Malik says, “If you don't lecture me.” The counsellor reflects, “You've had enough adults explaining your future at you.” He nods.

**Focusing.** Options are mapped: sleep, lessons, teachers, friends, coursework, home conflict. Malik chooses “mornings” as the least annoying focus.

**Evoking.** Importance of attending more is rated 4. Asked why not 1, Malik says he wants an apprenticeship and knows attendance is checked. Confidence is 3 because waking feels “impossible” and first lesson is with a teacher who publicly returns his work. Change talk emerges around competence and freedom: a reference from school would help him earn money and leave a neighbourhood conflict behind.

Sustain talk is explored respectfully. Staying home protects him from embarrassment and lets him help his grandmother. The counsellor reflects both sides rather than characterising home as avoidance.

**Information exchange.** With permission, the counsellor explains that the apprenticeship provider asks for attendance patterns but that late improvement still matters. Malik asks whether arriving for second lesson “counts for anything”; together they check school policy rather than speculate.

**Planning.** Malik chooses a two-week experiment: attend Tuesday to Friday from second lesson, sleep routine on school nights, phone charging downstairs on two nights he selects, and a private arrangement with the teacher to receive written feedback before any public comment. His mother agrees not to deliver morning lectures, replacing them with one agreed prompt and transport money placed by the door.

**Review.** Attendance rises to 70 per cent. More importantly, Malik describes himself as “testing whether I can do it”, not obeying the counsellor. When a setback follows a classroom humiliation, the process returns to evoking rather than blame.

## 10. Evidence and Research Support

Meta-analyses support MI for substance use and several health behaviours, with generally small to moderate effects that vary by outcome, fidelity, population, and comparison condition. Evidence with adolescents is promising for alcohol and substance use, treatment engagement, health behaviour, and some school applications, but heterogeneous.

MI is often brief and can enhance other treatments. It is not, by itself, sufficient treatment for severe depression, trauma, psychosis, eating disorders, or entrenched conduct problems. Effects decay when practitioners drift into persuasion, when fidelity is low, or when the environment makes chosen change practically impossible.

Training requires practice and feedback. Reading about empathy does not produce reflective listening. Audio review, coding, supervision, and coaching are associated with better skill retention than one-off workshops.

## 11. Strengths, Limitations, and Ethics

Strengths include respect for autonomy, usefulness at treatment entry, compatibility with other models, and attention to language as a mechanism of change. MI helps practitioners notice their own contribution to resistance.

Limitations include potential overfocus on individual choice where structural barriers dominate. A young person cannot choose safe housing into existence, make an inaccessible curriculum accessible, or remove discriminatory discipline by motivation alone. MI must therefore be paired with advocacy and practical support.

Ethically, practitioners must not use MI techniques to manufacture consent, conceal institutional goals, or evade safeguarding. Affirmations must be genuine. Reflections must not twist meaning. Summaries must

not erase sustain talk or dissent. The young person should know the counsellor's role, reporting obligations, and any non-negotiable requirements.

## 12. Key Terms

**Key Terms at a Glance**

- **Ambivalence** — Simultaneous reasons for and against change.
- **Change talk** — Client language favouring change.
- **Sustain talk** — Client language favouring the status quo or opposing change.
- **Fixing reflex** — The practitioner's premature urge to solve and persuade.
- **Elicit–provide–elicit** — A respectful sequence for exchanging information.
- **Agenda mapping** — Collaborative identification and prioritisation of possible change topics.
- **Epistemic humility in MI** — Recognition that the client is the primary expert on their values and life.

## 13. Chapter Summary

Motivational interviewing treats resistance less as a client trait than as a signal about the conversation. By partnering with adolescents, reflecting ambivalence, evoking their own reasons and values, and supporting feasible plans, the counsellor makes change speakable without making it compulsory. Its discipline is ethical as well as technical: influence must remain transparent, autonomy real, and safeguarding honest.

## 14. Review and Discussion Questions

**Review and Discussion Questions**

1. Why does arguing for change often strengthen sustain talk?
2. Distinguish preparatory from mobilising change talk.
3. Write a complex reflection for: “My mum goes on about vaping because she wants to control everything.”
4. Why ask why an importance rating is not lower before asking what would raise it?
5. How should MI be adapted for a mandated adolescent client?
6. When is advice-giving compatible with MI?
7. Identify one structural barrier that MI alone cannot solve.

## 15. Practice Activities

**Practice and Application**

### Activity 44.1 — Reflection practice

Convert five closed questions into open questions and complex reflections.

### Activity 44.2 — Ruler interview

In pairs, use importance and confidence rulers about a low-stakes habit. Practise asking why the number is not lower.

### Activity 44.3 — Spirit audit

Review a fictional transcript and mark partnership, acceptance, compassion, empowerment, and the fixing reflex.

## 16. Annotated Reading Pathways

**For foundations.** Miller and Rollnick's fourth edition is the most current comprehensive statement.

**For adolescents.** Naar and Suarez provide developmental and family adaptations, including work with caregivers.

**For schools.** Rollnick and colleagues show how brief MI conversations can be used without turning teachers into therapists.

**For evidence.** Read meta-analyses critically, noting fidelity measurement and whether MI was stand-alone or an engagement prelude.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Motivational Interviewing** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is miller and Rollnick's four processes, change talk, and the adolescent adaptation of a conversational method. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is development, agency, identity, culture, relationships, motivation, and ecological resources. The mechanism to keep in view is how beliefs, social models, environments, power, belonging, and developmental timing interact to support or restrict change. The characteristic professional risk is individualising structural harm, stereotyping culture, or demanding resilience while leaving unsafe conditions unchanged. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in schools, families, peer contexts, community services, and culturally responsive practice, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Marcus is fifteen and is seen in a community adolescent clinic for grief following a major family change. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Marcus's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The

practitioner first establishes safety, consent, and context. Marcus explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on development, agency, identity, culture, relationships, motivation, and ecological resources. The first intervention is deliberately modest. Marcus chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Marcus has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Marcus can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.

- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Motivational Interviewing

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Motivational Interviewing** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

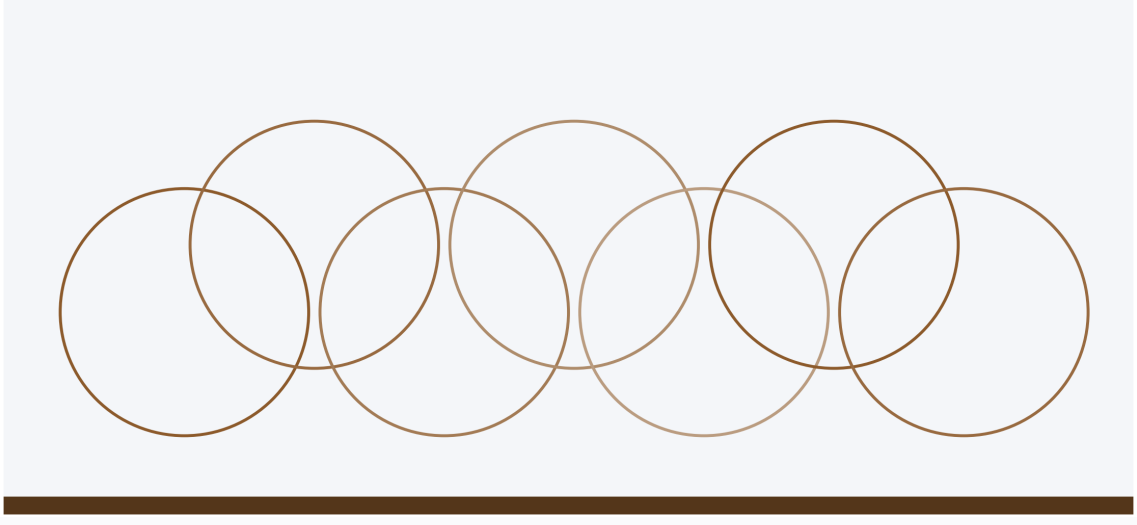
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a

recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Motivational Interviewing** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Motivational Interviewing**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Motivational Interviewing to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

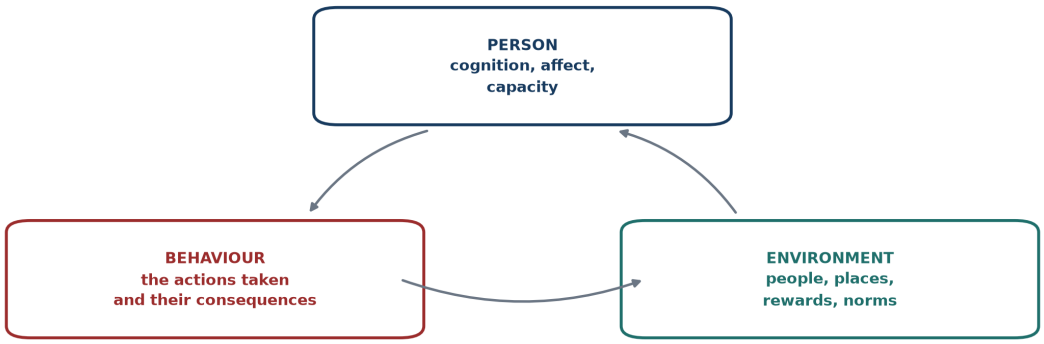
CHAPTER 45

# Social Cognitive Learning Theory

Bandura's reciprocal determinism, self-efficacy, and the modelling of behaviour in social contexts.

## Learning Objectives

By the end of this chapter, the student should be able to:



- Explain Bandura's move from social learning theory to social cognitive theory.
- Describe reciprocal determinism among person, behaviour, and environment.
- Define self-efficacy and identify its four sources.
- Distinguish outcome expectations, goals, self-regulation, and observational learning.
- Apply social cognitive theory to academic behaviour, peer influence, aggression, health, digital life, and therapeutic change.
- Design interventions that build mastery rather than merely encourage confidence.
- Evaluate limitations, cultural considerations, and ethical concerns.

## Chapter Overview

Albert Bandura transformed learning theory by insisting that people are not merely shaped by rewards and punishments. They observe, anticipate, interpret, set goals, judge their capabilities, regulate themselves, and alter the environments that alter them. Social cognitive theory therefore bridges behavioural and cognitive traditions while retaining a strong interest in social context.

For adolescent counselling, the theory is exceptionally practical. Young people learn from peers, siblings, influencers, teachers, fictional characters, and adults who may not know they are modelling. They avoid tasks not only because they lack skill but because they expect humiliation. They repeat behaviour because it produces status. They may know what to do yet lack confidence, opportunity, feedback, or a setting in which the behaviour is safe.

**Reciprocal Determinism: Person, Behaviour, and Environment**

*The three influences act on one another continuously; none is sufficient alone.*

**Figure 45.34** Reciprocal determinism: personal factors, behaviour, and environment continually influence one another.

## 1. From Modelling to Agency

Bandura's early experiments demonstrated observational learning: children who saw a model behave aggressively could reproduce novel aggressive acts, especially when the model was rewarded or held status. Later theory expanded beyond imitation. Human agency involves intentionality, forethought, self-reactiveness, and self-reflectiveness.

People act as contributors to their own development. But agency is not unlimited free will. A young person in poverty, unsafe housing, discriminatory schooling, or coercive relationships has real constraints. Social cognitive theory is strongest when the reciprocal model includes those constraints rather than converting every outcome into a test of personal belief.

## 2. Reciprocal Determinism

Personal factors (beliefs, affect, biology, knowledge), behaviour, and environment influence one another bidirectionally.

A student believes she is “bad at maths” (person). She avoids practice and hides confusion (behaviour). The teacher gives less feedback and peers become the audience for jokes about failure (environment). The belief strengthens. Intervention can enter at any point: mastery practice, teacher feedback routines, peer grouping, success experiences, or reinterpretation of difficulty.

This model prevents simplistic counselling. Telling the student to “believe in yourself” addresses one corner while leaving task design and classroom humiliation intact.

## 3. Observational Learning

Observational learning requires attention, retention, reproduction, and motivation.

**Attention** depends on salience, status, similarity, emotional arousal, and complexity. Adolescents often attend more to peers and online creators than to adults.

**Retention** involves symbolic coding and rehearsal. A young person may remember a humiliating comeback word for word and forget safety instructions.

**Reproduction** requires capability and opportunity. Watching assertiveness is not the same as having language, timing, and social permission to use it.

**Motivation** depends on observed and expected consequences. If aggression produces laughter and status, moral instruction alone competes poorly.

Counselling can therefore select models carefully: credible peers, coping models who struggle and improve, video self-modelling, teacher modelling of repair, and parent modelling of calm disagreement.

## 4. Self-Efficacy

Self-efficacy is belief in one's capability to organise and execute actions required for a specific task in a specific context. It is not general self-esteem. A student may have high efficacy for football and low efficacy for speaking in class.

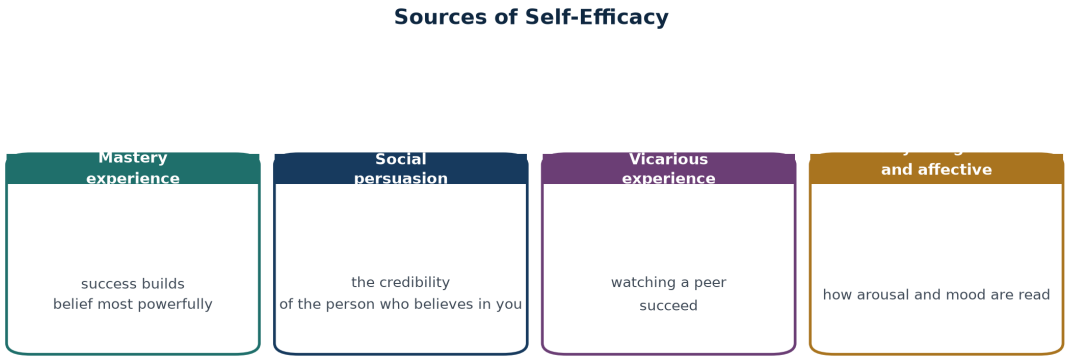


**Figure 45.35** Sources of self-efficacy: mastery experiences, vicarious experience, verbal persuasion, and physiological or affective states.

### 4.1 Mastery experiences

Successful performance is the strongest source, especially when success follows effort on a meaningful challenge and is attributed to strategy and capability. Tasks must be graded. Artificially easy praise produces fragile confidence.

### 4.2 Vicarious experience

Seeing someone similar succeed raises efficacy; seeing similar peers fail can lower it. Similarity matters: age, background, disability, gender, prior attainment, and social identity may affect identification.

### 4.3 Verbal persuasion

Encouragement helps when credible, specific, and paired with attainable steps. Empty reassurance can backfire after failure.

### 4.4 Physiological and affective states

Anxiety, fatigue, pain, excitement, and calm are interpreted as information about capability. Young people can learn to distinguish arousal from inability: a racing heart before speaking may signal importance, not inevitable failure.

## 5. Outcome Expectations, Goals, and Self-Regulation

People ask not only “Can I do it?” but “What will happen if I do?” Positive outcome expectations may involve grades, status, safety, belonging, money, freedom, or adult trust. Negative expectations may involve ridicule, punishment, exclusion, or loss of identity.

Goals organise behaviour when they are specific, challenging but attainable, proximal, and connected to feedback. Distal goals such as “get into college” rarely regulate a tired Tuesday evening. Proximal

goals—complete two problems, attend first lesson, revise for fifteen minutes—create mastery information.

Self-regulation includes self-observation, judgement against standards, and self-reaction. Diaries, apps, checklists, teacher feedback, and self-graphing make progress visible. Standards should be developmental and humane; perfectionistic self-monitoring can become another source of shame.

# 6. Further Reading for This Chapter

- Pajares, F. (1996). Self-efficacy beliefs in academic settings. *Review of Educational Research, 66*(4), 543–578.

# 7. Clinical and Educational Applications

## 7.1 Academic avoidance

A social cognitive formulation asks:

- What specific task efficacy is low?
- What outcomes are expected from trying and failing?
- Which models dominate?
- What mastery opportunities exist?
- How do teachers and peers respond to error?
- Which self-regulation tools are available?
- What environmental barriers can be changed?

Intervention might include graded tasks, worked examples, peer coping models, private feedback before public performance, strategy attribution (“the plan worked”), and visible progress records.

## 7.2 Aggression and peer status

Aggression may be maintained by efficacy beliefs (“I can make them back down”), outcome expectations (“respect requires retaliation”), modelling, moral disengagement, and environments that reward dominance. Intervention must change status economies, not only teach anger facts. Schools can create legitimate routes to competence and recognition, use restorative processes where safe, involve credible peer models, and ensure adults do not model humiliation.

## 7.3 Health and digital behaviour

Young people observe sleep, eating, exercise, vaping, sexual behaviour, and risk through families, peers, and algorithmic media. Social cognitive work identifies models, outcome expectations, and environmental

cues. A plan to reduce late-night phone use is stronger when it alters charging location, peer response norms, replacement activities, and morning goals than when it relies on warnings.

### 7.4 Therapeutic change

Many therapies work partly by increasing efficacy. Exposure creates mastery. Skills training provides models and rehearsal. Behavioural activation generates success experiences. Parent training increases parental efficacy. MBT improves confidence that mental states can be understood. Social cognitive theory therefore integrates mechanisms across this book.

## 8. Case Illustration: The Student Who Would Not Present

**Presentation.** Priya, thirteen, refuses oral presentations. She is articulate with friends and writes well. She says, “I'm just not a confident person.”

**Formulation.** Her presentation-specific efficacy is low after freezing during a primary-school assembly. She expects peers to laugh and teachers to think she is lazy. She watches confident classmates and concludes they are naturally different. Physiological arousal is interpreted as proof she will forget everything. Avoidance prevents corrective mastery.

**Intervention.** The counsellor and teacher design a mastery ladder: record a thirty-second voice note; present to the counsellor; present to one trusted friend; read one paragraph to a small group; answer one prepared question; present two slides. A coping model video shows a similar student pausing, breathing, and recovering after losing place. Feedback identifies strategies used, not personality traits. Arousal is reframed as activation that can coexist with performance.

Environmental changes matter. The teacher stops surprise questioning during the ladder, permits cue cards, and arranges the first small-group audience. Peers are given roles as summariser and questioner rather than evaluators.

**Outcome.** Priya completes a three-minute group presentation. She remains nervous and does not become “a confident person” in general. Her belief becomes precise: “I can present if I prepare, start small, and know how to recover.” That precision is the therapeutic achievement.

## 9. Evidence and Limitations

Self-efficacy predicts academic performance, persistence, health behaviour, career exploration, and treatment outcomes across many studies. Interventions that create mastery and credible modelling can change efficacy and behaviour, though effects vary and reciprocal causality makes simple interpretation difficult: success raises efficacy, and efficacy supports success.

Observational learning is robustly established, but popular claims about media effects require nuance. Exposure to aggressive or risky models interacts with prior disposition, family context, peer norms, identification, reward, and opportunity. Social cognitive theory does not justify moral panic or censorship by itself.

Limitations include measurement by self-report, cultural variation in agency and selfhood, and risk of blaming individuals for structural constraints. In collectivist contexts, efficacy may be experienced as

collective efficacy—"we can do this"—rather than solitary confidence. Interventions should therefore assess family, peer, school, and community efficacy.

## 10. Cultural and Ethical Considerations

Models are not neutral. Representation matters: who is shown succeeding, whose behaviour is labelled leadership or defiance, and which futures appear imaginable. Counsellors should use diverse, credible models and avoid tokenism.

Verbal persuasion must not become pressure. Encouraging a young person to attempt an unsafe disclosure, confront an abuser, or perform beyond disability-related capacity in the name of confidence is unethical. Mastery must be designed with accessibility, safeguarding, and realistic resources.

Digital modelling raises consent issues. Video self-modelling and peer examples require permission, secure storage, and attention to embarrassment. Public progress charts can motivate some students and humiliate others; private feedback should be default where stigma is likely.

## 11. Key Terms

**Key Terms at a Glance**

- **Reciprocal determinism** — Bidirectional influence among person, behaviour, and environment.
- **Observational learning** — Learning through attention, retention, reproduction, and motivation.
- **Self-efficacy** — Task- and context-specific belief in one's capability to execute required actions.
- **Mastery experience** — Successful performance that provides evidence of capability.
- **Collective efficacy** — A group's shared belief in its capacity to act effectively.
- **Outcome expectation** — Belief about likely consequences of a behaviour.
- **Coping model** — A model who visibly struggles, corrects errors, and improves.

## 12. Chapter Summary

Social cognitive theory explains why young people do not simply do what they know. They watch, infer, anticipate, judge capability, pursue status and safety, and act within environments that answer back. Effective counselling changes more than belief: it engineers mastery, selects models, alters consequences, teaches self-regulation, and removes barriers.

## 13. Review and Discussion Questions

**Review and Discussion Questions**

1. Apply reciprocal determinism to school refusal.
2. Why is self-efficacy not the same as self-esteem?
3. Rank the four sources of efficacy for a student returning after long absence, and justify the ranking.
4. What makes a coping model more useful than a flawless model?
5. Identify one intervention each at the person, behaviour, and environment points of a case.
6. How can collective efficacy change an intervention plan?
7. State one ethical risk of video modelling with adolescents.

## 14. Practice Activities

**Practice and Application**

### Activity 45.1 — Efficacy ladder

Choose a specific avoided task and design six mastery steps with feedback and attribution at each step.

### Activity 45.2 — Model audit

List the five most influential models in a fictional adolescent's digital and offline life. Identify what each model teaches and what consequences follow.

### Activity 45.3 — Reciprocal map

Draw person–behaviour–environment influences for aggression maintained by peer status.

## 15. Annotated Reading Pathways

**For theory.** Bandura (1986) remains the comprehensive source; Bandura (1997) is essential for self-efficacy.

**For education.** Pajares and Schunk connect efficacy to classroom design, feedback, and achievement.

**For practice.** Translate every encouragement into a mastery opportunity, credible model, or environmental change. If none exists, the intervention is probably only exhortation.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Social Cognitive Learning Theory** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is bandura's reciprocal determinism, self-efficacy, and the modelling of behaviour in social contexts. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is development, agency, identity, culture,

relationships, motivation, and ecological resources. The mechanism to keep in view is how beliefs, social models, environments, power, belonging, and developmental timing interact to support or restrict change. The characteristic professional risk is individualising structural harm, stereotyping culture, or demanding resilience while leaving unsafe conditions unchanged. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

## A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in schools, families, peer contexts, community services, and culturally responsive practice, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach,

peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Leah is fifteen and is seen in a family support service for sleep disruption, irritability, and falling participation. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Leah's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Leah explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on development, agency, identity, culture, relationships, motivation, and ecological resources. The first intervention is deliberately modest. Leah chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Leah has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Leah can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the

young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language;

the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Social Cognitive Learning Theory

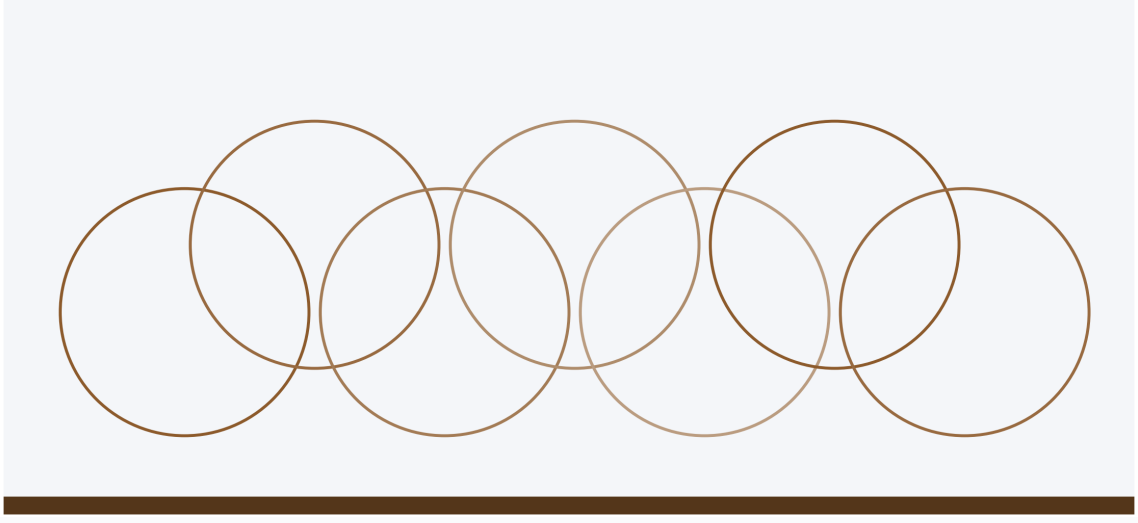
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Social Cognitive Learning Theory** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Social Cognitive Learning Theory** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Social Cognitive Learning Theory**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Social Cognitive Learning Theory to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 46

# Adolescent Development: Theory and Counseling Implications

Identity, autonomy, risk, and peer relations as a developmental framework for intervention.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Describe adolescent development across biological, cognitive, emotional, social, moral, and identity domains.
- Explain puberty, brain development, sleep changes, and heightened reward sensitivity without reducing adolescence to hormones or defective decision-making.
- Compare major developmental theories and identify their counselling implications.
- Explain identity formation, autonomy, peer belonging, family renegotiation, sexuality, and digital development.
- Recognise diversity in developmental pathways, including disability, chronic illness, migration, poverty, care experience, and cultural variation.
- Formulate presenting problems developmentally rather than treating adolescence itself as pathology.
- Apply developmental knowledge to assessment, timing, confidentiality, family work, and school consultation.

## Chapter Overview

Adolescence is not a waiting room between childhood and adulthood. It is a developmental period with its own tasks, sensitivities, opportunities, and risks. Young people are biologically maturing, thinking more abstractly, forming identity, renegotiating family dependence, seeking peer belonging, exploring sexuality and values, and preparing for adult roles—all while adults still control many conditions of their lives.

Counsellors who misunderstand development make predictable errors. They treat normal autonomy seeking as oppositional pathology; interpret concrete thinking as resistance; expect adult-like emotional regulation from a sleep-deprived fourteen-year-old; disclose information to parents as if the client were eight; or impose independence as if the client were twenty-five. Developmental formulation protects against both infantilisation and premature adultification.

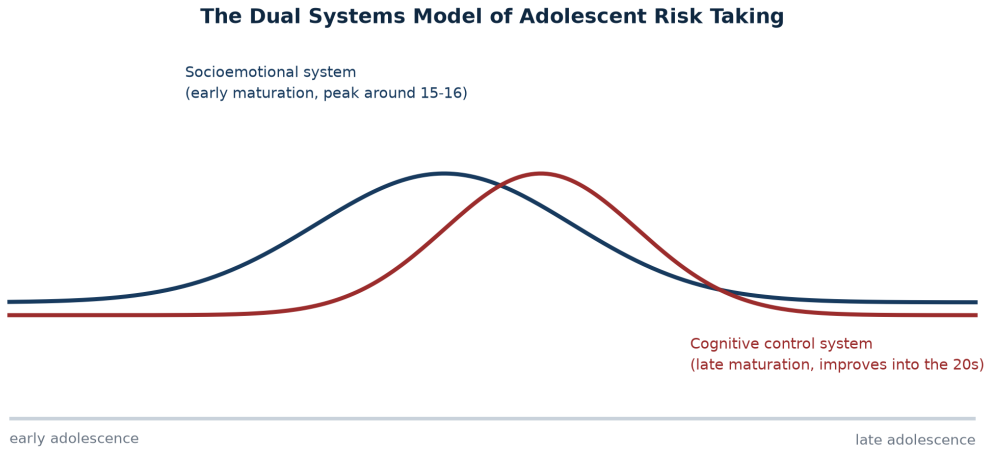


**Figure 46.36** Adolescent dual-systems development: heightened reward and peer sensitivity alongside gradually maturing cognitive control, with context determining balance.

# 1. What Is Adolescence?

Chronological boundaries vary. Many contemporary accounts describe adolescence as approximately ten to twenty-four, recognising extended education, later financial independence, and continued brain development. Legal, cultural, educational, and family transitions do not align neatly. A married seventeen-year-old worker, a thirteen-year-old in secondary school, and a twenty-two-year-old university student may all be called adolescents or young people while facing very different tasks.

Development is also asynchronous. Puberty may be early while emotional regulation is young; abstract reasoning may be strong while social confidence is fragile; sexual maturity may precede access to accurate information or safe relationships. Assessment should ask, domain by domain, “Where is this young person developmentally?” rather than assume age answers the question.

# 2. Biological Development

## 2.1 Puberty

Puberty involves hormonal changes, growth, sexual maturation, body hair, skin changes, menstruation, voice change, and altered body composition. Timing matters. Early or late maturation can affect peer status, adult expectations, body image, sexualisation, and risk. Adults may treat a physically mature child as emotionally older, a pattern sometimes called adultification, with serious safeguarding implications.

Counsellors should ask sensitively about pubertal concerns, menstrual health, pain, acne, height, weight change, breast or genital development, and embarrassment in changing rooms or sport. Medical referral is appropriate where pain, delayed or precocious development, eating concerns, or distress require assessment.

## 2.2 Brain development

Adolescent brain development includes synaptic pruning, myelination, changing reward sensitivity, and gradual strengthening of prefrontal systems involved in planning, inhibition, and long-term consequence evaluation. The popular “dual systems” account contrasts heightened socioemotional and reward sensitivity with still-maturing cognitive control.

This model is useful but incomplete. Adolescents can reason well in calm, supported conditions and make poorer decisions when peers are present, emotions are high, time is short, or rewards are immediate. Adults do the same, albeit often less intensely. The implication is not that adolescents are incapable; it is that environments should reduce unnecessary heat: sleep, time to decide, private rather than public correction, limited audience, and adults who do not force instant answers during conflict.

## 2.3 Sleep

Puberty shifts circadian preference later while school often starts early. Sleep deprivation impairs mood, learning, impulse control, pain tolerance, and family patience. Assessment that ignores sleep is incomplete. Counsellors should ask about bedtime, waking, naps, screens, caffeine and energy drinks, shift-working parents, shared rooms, nightmares, snoring, and weekend catch-up patterns.

Sleep intervention is developmental work: regular wake time, morning light, reduced late caffeine, planned screen transitions, treatment of anxiety or medical problems, and school advocacy where start times or travel make adequate sleep impossible.

## 3. Cognitive Development

Adolescents increasingly use abstract, hypothetical, and metacognitive thought. They can imagine alternative selves, question rules, detect hypocrisy, and reason about justice. This is not merely a risk; it is an intellectual achievement.

At the same time, abstract capacity is uneven. A young person may debate politics brilliantly and think concretely about contraception, debt, or online permanence. Stress narrows cognition. Neurodevelopmental conditions, trauma, language development, and educational opportunity shape expression.

Counselling should therefore check understanding rather than infer it from vocabulary. Ask the young person to explain a plan in their own words. Use examples, drawings, scaling, timelines, and written summaries. Do not mistake fluent therapy language for integrated understanding.

## 4. Emotional Development

Emotional intensity, self-consciousness, and sensitivity to evaluation increase. Shame becomes a powerful organising emotion because identity and peer status are at stake. Emotional regulation develops through co-regulation, practice, sleep, language, and environments that do not continually overwhelm.

The adolescent may oscillate between wanting comfort and rejecting it. A parent offers a hug; the young person recoils, then later sits nearby while pretending to watch television. Counsellors and parents need to read proximity flexibly and not demand that care be accepted in adult-preferred forms.

Emotional development is also cultural. Families differ in expression, restraint, humour, privacy, and help seeking. Assessment should ask what feelings are acceptable at home, which are hidden, and what happens when someone cries, protests, or becomes quiet.

## 5. Identity Development

Erikson placed identity versus role confusion at the centre of adolescence. Contemporary accounts are less linear. Identity includes ethnicity, culture, language, gender, sexuality, disability, faith-neutral value commitments where personally chosen, class, nationality, family story, interests, body, and future occupation. Exploration and commitment interact over time, and identity may be revisited throughout life.

Marcia described statuses based on exploration and commitment: diffusion, foreclosure, moratorium, and achievement. These are heuristics, not diagnoses. A young person may be exploratory about career, foreclosed about family values, and uncertain about gender or sexuality. Safety affects exploration: it is not developmental failure when a young person conceals identity in an unsafe home or community.

Counselling supports identity by providing language, mirrors, time, and non-possessive curiosity. The counsellor does not assign an identity, rush disclosure, or treat questioning as a phase to be corrected.

- Erikson, E. H. (1968). *Identity: Youth and Crisis*.

## 7. Family Autonomy and Relatedness

Healthy adolescent development is not separation from family but transformation of family relationships. Autonomy grows best with relatedness: the young person can disagree, make choices, and spend time elsewhere while retaining connection and support.

Parents often experience ordinary autonomy as loss or disrespect. The adolescent experiences parental protection as control or distrust. Both may be partly right. Counselling helps families distinguish safety rules from habits of childhood, negotiate graduated freedoms, and repair after conflict.

Key questions include:

- Which decisions does the young person already make well?
- Which freedoms are linked to demonstrated skills rather than age alone?
- What information do parents genuinely need for safety?
- What privacy is developmentally appropriate?
- How are mistakes handled—by teaching and proportionate consequence, or by total withdrawal of trust?

Families under stress may have fewer resources for gradual negotiation. Poverty, unsafe neighbourhoods, parental illness, migration, and caring responsibilities can require adolescents to mature early in some domains while remaining dependent in others.

## 8. Peers, Romance, and Digital Life

Peer belonging is a developmental need, not a distraction from real life. Friendship teaches reciprocity, loyalty, repair, status, intimacy, and boundary setting. Peer rejection and bullying can therefore have profound effects.

Romantic and sexual development involves curiosity, attraction, consent, communication, body image, and values. Counsellors should provide non-shaming, medically accurate, safeguarding-aware practice and know local law and referral pathways. The counsellor does not facilitate secrecy that places a young person at risk, nor disclose lawful private information merely to satisfy adult anxiety.

Digital environments are social environments. Group chats, gaming, social platforms, image sharing, pornography, influencers, and algorithmic recommendation shape identity and comparison. Assessment should ask what platforms do for the young person—belonging, creativity, learning, escape, status—as well as what they cost. A purely confiscatory response may remove support as well as risk.

## 9. School and Future Development

School is simultaneously an educational institution, peer society, evaluation system, and route to future opportunity. Academic identity forms through feedback, grouping, teacher relationships, curriculum

relevance, language, disability access, and experiences of success.

Developmental counselling asks whether demands match capacity and support. A student may fail because work is too difficult, too easy, inaccessible, publicly humiliating, poorly timed for sleep, or irrelevant to any imaginable future. Motivation cannot be separated from curriculum and relationship.

Career development begins long before formal choices. Young people need exposure to possibilities, work experience, adults who imagine futures for them, and freedom from premature narrowing based on class, gender, race, disability, or school predictions.

## 10. Developmental Formulation in Counselling

A developmental formulation includes:

1. pubertal and health context;
2. sleep, energy, pain, and medication;
3. cognitive and language capacities;
4. emotional regulation and co-regulation;
5. identity exploration and safety;
6. family autonomy–relatedness balance;
7. peer belonging and digital life;
8. school fit and future orientation;
9. culture, migration, faith-neutral values where relevant, and community resources;
10. strengths, interests, and developmental opportunities.

The formulation should lead to timing decisions. Some work is best done individually, some with parents, some through school change, and some deferred until sleep, safety, or stability improves. A developmentally appropriate plan does not demand that a young person solve in therapy what adults must solve in the environment.

## 11. Case Illustration: “Lazy, Rude, and Always on That Phone”

**Presentation.** Daniel, fourteen, is referred for oppositional behaviour. He sleeps until noon at weekends, argues when woken, ignores homework, and becomes angry when his phone is removed at midnight.

**Developmental assessment.** Daniel's circadian rhythm has shifted later; school requires waking at 6:15 a.m. He is chronically sleep deprived. Puberty has made him highly sensitive to public correction; two teachers use sarcasm. His phone is not merely entertainment but the location of his friendship group after his best friend moved school. At home he is given few choices but is expected to show adult self-control when tired.

**Formulation.** The presenting behaviour is interaction among sleep biology, peer belonging, autonomy needs, family control patterns, and school humiliation—not a unitary oppositional trait.

**Intervention.** The family negotiates a sleep plan: fixed wake time, phone charging outside the bedroom after an agreed time, but protected group-chat time earlier in the evening. His mother replaces repeated morning calls with one prompt, light, breakfast, and a predictable departure routine. School agrees to private correction and a seating change. Daniel chooses a football activity that restores peer contact offline.

Daniel remains argumentative at times, especially when tired. The difference is that adults stop building a character diagnosis from predictable developmental friction and start changing timing, audience, and choices.

## 12. Evidence and Critical Considerations

Developmental science supports the importance of sleep, puberty timing, peer context, family autonomy support, school belonging, and sensitive periods for learning and stress. Brain research informs practice but should not be oversimplified into claims that adolescents cannot reason or that a brain scan can determine individual maturity.

Stage theories can become rigid. Young people do not pass through identical sequences at identical ages, and cultural pathways to adulthood differ. Competence may be domain-specific. A young parent, carer, worker, or migrant adolescent may hold adult responsibilities while still needing adolescent protection and support.

Adultification and infantilisation are both harmful. Adultification denies protection to young people perceived as older, often along racialised and gendered lines. Infantilisation denies agency and privacy. Ethical assessment continually asks: What protection does this young person need? What agency can they exercise? What support makes both possible?

## 13. Key Terms

**Key Terms at a Glance**

- **Adultification** — Treating a child or adolescent as older and less in need of protection than they are.
- **Autonomy–relatedness** — The developmental balance between self-direction and continuing family connection.
- **Circadian shift** — Puberty-associated tendency toward later sleep and waking times.
- **Developmental formulation** — Explanation of difficulties in relation to developmental capacities, tasks, contexts, and timing.
- **Dual-systems model** — Account of adolescence emphasising reward sensitivity and maturing cognitive control.
- **Identity exploration** — Active consideration of values, roles, identities, and possible futures.
- **School belonging** — The experience of being accepted, respected, and able to participate in school life.

## 14. Chapter Summary

Adolescent counselling begins when adults stop asking only, “How do we stop this behaviour?” and ask also, “What developmental work is this young person attempting, under what biological, relational, cultural, and institutional conditions?” Development does not excuse harm, but it explains timing, sensitivity, and the kinds of support that make change possible.

## 15. Review and Discussion Questions

**Review and Discussion Questions**

1. Explain why adolescence should not be treated as either childhood or adulthood.
2. How can the dual-systems model be used without stereotyping adolescents?
3. Identify four ways sleep deprivation can masquerade as behavioural disorder.
4. Distinguish autonomy from separation.
5. Why is peer belonging a developmental need rather than a reward?
6. Write a developmental formulation for a fifteen-year-old school refuser.
7. Give one example each of adultification and infantilisation in services.

## 16. Practice Activities

**Practice and Application**

### Activity 46.1 — Developmental map

Create a domain-by-domain developmental map for a fictional fifteen-year-old: body, sleep, cognition, emotion, identity, family, peers, digital life, and school.

### Activity 46.2 — Environment redesign

Take a common conflict about homework and redesign timing, audience, choice, feedback, and sleep rather than focusing only on motivation.

### Activity 46.3 — Language audit

Rewrite five adult statements that label an adolescent as lazy, manipulative, dramatic, or attention-seeking into developmental observations.

## 17. Annotated Reading Pathways

**For comprehensive development.** Steinberg and Arnett provide complementary biological and cultural accounts.

**For brain development.** Blakemore is accessible and careful; use primary neuroscience reviews to avoid pop-neuroscience claims.

**For identity.** Erikson and Marcia are historically important but should be read alongside contemporary work on culture, gender, sexuality, disability, and migration.

**For practice.** Translate every developmental claim into an assessment question, an environmental adjustment, or a timing decision.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Adolescent Development: Theory and Counseling Implications** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is identity, autonomy, risk, and peer relations as a developmental framework for intervention. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is development, agency, identity, culture, relationships, motivation, and ecological resources. The mechanism to keep in view is how beliefs, social models, environments, power, belonging, and developmental timing interact to support or restrict change. The characteristic professional risk is individualising structural harm, stereotyping culture, or demanding resilience while leaving unsafe conditions unchanged. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in schools, families, peer contexts, community services, and culturally responsive practice, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the

result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Tobias is fifteen and is seen in an integrated school and health team for conflict with parents about autonomy. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Tobias's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Tobias explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on development, agency, identity, culture, relationships, motivation, and ecological resources. The first intervention is deliberately modest. Tobias chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Tobias has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Tobias can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by

participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?

- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Adolescent Development: Theory and Counseling Implications

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Adolescent Development: Theory and Counseling Implications** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

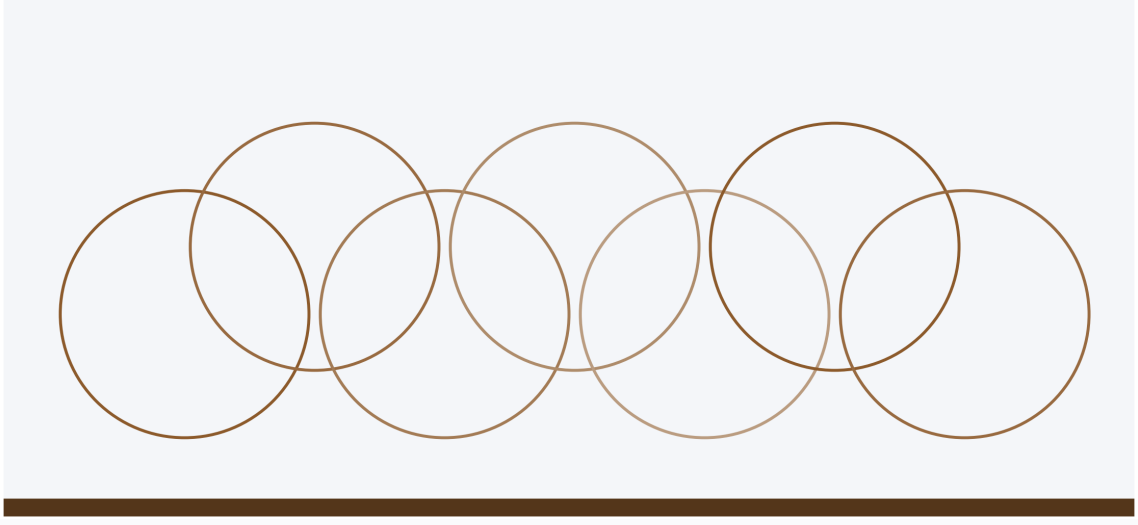
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Adolescent Development: Theory and Counseling Implications** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Adolescent Development: Theory and Counseling Implications**, and the response of the



surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Adolescent Development: Theory and Counseling Implications to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 47

# Psychodynamic and Object Relations Approaches

The relational substrate of personality, transference, and developmental lines of interpretation.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Describe the development of psychodynamic thinking from Freud through ego psychology, object relations, self psychology, and relational approaches.
- Explain unconscious processes, conflict, defence, transference, countertransference, and enactment in clinically usable language.
- Describe object relations concepts: internal objects, splitting, projection, projective identification, and containment.
- Apply psychodynamic formulation to adolescent identity, family relationships, school behaviour, and therapeutic ruptures.
- Distinguish evidence-informed psychodynamic practice from unfalsifiable interpretation.
- Recognise cultural, ethical, and safeguarding limits.

## Chapter Overview

Psychodynamic approaches ask how earlier relationships, conflicted wishes and fears, defences, and unconscious patterns continue to organise present experience. Their language can appear remote from school corridors and family kitchens, yet their central observations are familiar. A student experiences a neutral teacher as contemptuous. A parent reacts to a fifteen-year-old as if she were still seven—or as if she were the parent's own critical mother. A counsellor feels an inexplicable urge to rescue, punish, withdraw, or become unusually helpless. Psychodynamic practice slows these moments down and asks what relational pattern is being repeated, avoided, or communicated.

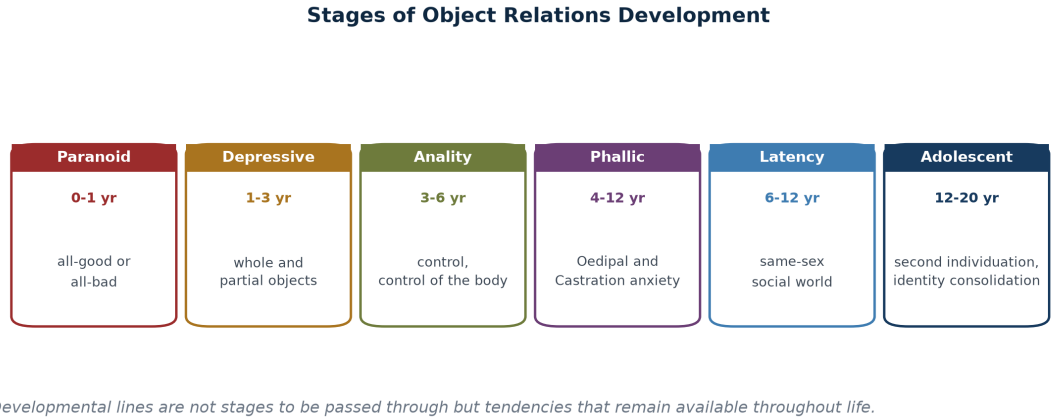


**Figure 47.37** Object relations patterns: early relational experiences become internal templates that shape expectations of self and other.

## 1. Historical Development

Freud's work introduced the ideas that mental life includes unconscious processes, that symptoms may express conflict, that childhood experience matters, and that the therapeutic relationship itself becomes a

field in which old patterns appear. Many specific Freudian claims have been revised or rejected, but the clinical attention to hidden meaning, ambivalence, defence, and repetition remains influential.

Ego psychology emphasised adaptation, defence analysis, and strengths of the ego. Object relations theorists—including Klein, Fairbairn, and Winnicott—shifted attention toward internalised relationships: the self in relation to “objects”, meaning significant others as represented in the mind. Self psychology, associated with Kohut, emphasised empathy, self-cohesion, and needs for mirroring, idealisation, and belonging. Relational and intersubjective approaches later stressed that therapy is co-created by two subjectivities rather than observed from outside by a neutral analyst.

Adolescent psychodynamic work must be developmentally flexible. Long silences, free association, and couch-based adult psychoanalysis are not automatically appropriate. Young people often need activity, clarity, family involvement, school liaison, humour, and explicit safety structures.

# 2. Core Concepts

## 2.1 Unconscious processes

Unconscious does not mean a mystical basement of forbidden content. In contemporary practice it includes processes outside awareness: automatic expectations, disowned feelings, procedural relational patterns, avoided memories, and motives that conflict with the person's self-image.

A student may consciously want to succeed yet repeatedly sabotage examinations because success feels disloyal to a struggling parent, exposes him to envy, or threatens an identity built around not caring. The counsellor does not announce this as fact. It becomes a tentative formulation tested against history, affect, repetition, and the young person's response.

## 2.2 Conflict and ambivalence

People can love and resent the same person, want independence and fear abandonment, desire success and dread visibility. Adolescence intensifies ambivalence because dependence and autonomy coexist.

Symptoms may compromise between wishes and prohibitions. School refusal can express fear, protect a depressed parent from loneliness, avoid humiliation, and punish controlling adults—all at once. A single-cause formulation may therefore be too thin.

## 2.3 Defences

Defences are psychological strategies that reduce awareness of painful feelings or conflict. They are adaptive in origin and costly when rigid.

- **Denial:** refusing to register reality.
- **Projection:** attributing one's disowned feeling to another.
- **Splitting:** experiencing self or others as all good or all bad.
- **Displacement:** redirecting feeling from a dangerous target to a safer one.
- **Intellectualisation:** discussing feeling abstractly to avoid experiencing it.
- **Humour:** transforming pain into shared perspective; it may be mature or avoidant depending on use.
- **Acting out:** communicating through action what cannot yet be thought or spoken.

The counsellor should describe defences compassionately. A defence is protection before it is pathology.

### 2.4 Transference and countertransference

Transference refers to the activation in therapy of expectations and feelings derived from earlier relationships. An adolescent may test whether the counsellor will become disgusted, intrusive, bored, rescuing, or abandoning.

Countertransference includes the counsellor's emotional responses, shaped both by the young person's interpersonal pull and by the counsellor's own history. It is data, not a command. Feeling bored may signal dissociation, hopelessness, practitioner fatigue, or an unspoken mismatch. Supervision prevents enactment.

### 2.5 Enactment and repetition

When patterns cannot be verbalised, they may be enacted. The counsellor is drawn into the role of critical parent, helpless child, rescuer, rival, or absent adult. Recognising enactment allows repair: “I notice I've started sounding like I'm cross-examining you. That may be exactly what happens at home. Let's pause.”

## 3. Object Relations and Internal Objects

An internal object is not a literal person inside the mind. It is an affect-laden representation of self in relation to another. A child repeatedly comforted develops an expectation that distress can be brought to someone and survived. A child repeatedly shamed may internalise a contemptuous other and a defective self.

These templates influence perception. Ambiguous teacher feedback is heard through the internal critic. A friend's silence activates an abandoning other. Therapy offers a new relational experience, but one relationship does not erase a template; repetition, reflection, family work, and real-world relationships all contribute.

Splitting may dominate under stress: one teacher is wonderful, another evil; mother is perfect until she sets a limit, then wholly cruel. Development involves integrating ambivalence—recognising that the same person can be loved, disappointing, safe, and limited.

## 4. Containment and Mentalization Links

Bion's concept of containment describes a caregiver receiving a child's unbearable state, tolerating and transforming it, and returning it in more manageable form. The parent who can hear panic without panicking or punishing helps the child learn that feeling can be thought about.

Psychodynamic adolescent practice often works through containment before interpretation. The counsellor remains present with rage, shame, or despair without retaliating, collapsing, or rushing to cheer up. Over time the young person internalises a more reflective relationship to their own states. This links psychodynamic work to attachment and mentalization approaches in Chapters 34 and 42.

# 6. Psychodynamic Assessment and Formulation

A psychodynamic formulation is a structured hypothesis, not a pronouncement. It may include:

1. **Presenting pattern:** What repeats across settings and relationships?
2. **Developmental history:** Early care, losses, separations, trauma, illness, school transitions, and strengths.
3. **Internal world:** Representations of self and others; dominant affects; feared and wished-for relationships.
4. **Conflicts:** Autonomy versus loyalty, anger versus need, success versus belonging, sexuality versus shame, dependence versus contempt.
5. **Defences:** How painful states are avoided or communicated.
6. **Transference possibilities:** What role may the counsellor be assigned?
7. **Family and social context:** What present realities sustain the pattern?
8. **Capacity and risk:** Reflection, affect tolerance, support, self-harm, safeguarding, and ability to use therapy.

The formulation should be revisable. If every response confirms the theory—agreement means insight and disagreement means resistance—the theory has become unfalsifiable and clinically dangerous.

# 7. Technique with Adolescents

## 7.1 Frame and reliability

Time, place, confidentiality, cancellations, digital contact, and endings carry meaning. Reliability is treatment, especially for young people whose adults have been unpredictable. Changes should be explained and repaired.

## 7.2 Play, activity, and metaphor

Younger adolescents may think through drawing, music, games, stories, sport, or shared tasks. The counsellor follows meaning without forcing symbolic interpretation. A drawing of a locked house may be a house, a memory, a wish for privacy, or all three.

### 7.3 Clarification before interpretation

Ask what happened, what was felt, what was feared, and what was expected. Interpretation, when used, should be tentative, brief, close to experience, and timed when affect is present but manageable. “Perhaps when your tutor went quiet, it felt like the criticism you brace for at home” is preferable to a grand claim about the unconscious.

### 7.4 Working with defences

Do not strip defences faster than alternatives develop. Intellectualisation may allow a young person to attend sessions at all. Humour may preserve dignity. Denial may be temporarily necessary after loss. The counsellor names cost and function: “Joking helps you stay in the room; it also means no one knows when you're actually frightened.”

### 7.5 Rupture and repair

Missed appointments, silence, anger at the counsellor, and disappointment are material. Repair requires acknowledgement, curiosity, and sometimes apology. A counsellor who can survive anger without retaliation offers a powerful corrective experience.

## 8. Case Illustration: The Boy Who Made Teachers Give Up

**Presentation.** Yusuf, fifteen, is described as bright but sabotaging. He begins coursework enthusiastically, then stops near completion. Teachers initially invest heavily, become frustrated, and withdraw. Yusuf says he does not care.

**History and pattern.** His father, a high-achieving professional, left the family after repeated conflict and now offers intense praise during brief visits followed by long silence. Yusuf longs for his father's recognition and protects himself by deciding in advance that effort is pointless. Teachers repeat the cycle: special encouragement, disappointment, withdrawal. Yusuf interprets withdrawal as proof that adults value performance, not him.

**Transference.** In counselling, Yusuf tests the frame. He misses a session after a particularly open conversation. The counsellor feels irritated and then unusually inclined to send a long reassuring message. In supervision, this is understood as a pull to become the idealising rescuer who will later feel betrayed.

**Intervention.** The counsellor maintains boundaries, acknowledges the missed session without punishment, and explores sequence rather than motive. Yusuf can say, “When I tell people things, they get weird.” The counsellor responds, “Perhaps leaving first felt safer than waiting to see whether I would become less interested.” Yusuf is quiet, then says, “That's what Dad does—goes quiet.”

Work includes practical study structure, teacher consultation to provide steady rather than inflated feedback, and a family session in which his mother stops mediating all contact with his father. Yusuf writes but does not send several letters, distinguishing expression from action.

**Outcome.** Coursework completion improves unevenly. The more important shift is relational: Yusuf can tell a teacher, “I need feedback before the final week or I shut down,” instead of disappearing.

Psychodynamic formulation did not replace practical planning; it explained why planning collapsed at the point of anticipated judgement.

## 9. Evidence and Limitations

Psychodynamic therapies have evidence for several adult conditions and growing evidence for children and adolescents, including short-term psychodynamic psychotherapy for adolescent depression in some trials and service evaluations. Effects depend on condition, severity, treatment length, and comparison care. Evidence is less strong where immediate behavioural control, skills acquisition, family contingency change, or crisis stabilisation is the urgent need.

The approach's concepts vary in empirical status. Attachment and defence processes have research support; broad claims about unconscious causation are harder to test. Good practice uses psychodynamic thinking as formulation and relationship discipline, not as licence to override the young person's account.

Duration and access are concerns. Open-ended therapy may be unavailable or unnecessary. Brief psychodynamic models, mentalization-based treatment, and integration with family and school work improve applicability.

## 10. Cultural and Ethical Considerations

Psychodynamic theories emerged largely from European and North American clinical contexts. Concepts of self, family obligation, emotional expression, sexuality, and authority are culturally shaped. A counsellor must not interpret collectivist loyalty as enmeshment, religiously grounded moral commitments as mere defence, or justified mistrust of institutions as projection.

Interpretation is an exercise of power. The practitioner should invite correction, use tentative language, and avoid claiming privileged access to the young person's true motives. Safeguarding information must not be reframed as fantasy or transference. Where abuse, coercion, or discrimination is occurring, present reality takes precedence.

Confidentiality and parental involvement require developmental judgement. Parents may need guidance on patterns without receiving session content. Endings should be planned carefully where abandonment themes are central; abrupt service termination can repeat the very pattern under treatment.

## 11. Key Terms

**Key Terms at a Glance**

- **Defence** — A psychological strategy that reduces awareness of painful affect or conflict.
- **Transference** — Activation in therapy of relational expectations derived from earlier experience.
- **Countertransference** — The practitioner's emotional responses within the therapeutic relationship, used reflectively rather than acted upon.
- **Internal object** — An affect-laden mental representation of self in relation to a significant other.
- **Splitting** — Experiencing self or others in all-good and all-bad terms under stress.
- **Projective identification** — A process in which disowned states are evoked in another person, who may be pressured to enact them.
- **Containment** — Receiving and transforming unbearable affect so it can be returned in thinkable form.
- **Enactment** — Repetition of a relational pattern in action before it can be verbalised.

## 12. Chapter Summary

Psychodynamic and object relations approaches teach counsellors to listen for repetition, ambivalence, defence, and the relational meanings of behaviour. With adolescents, their value lies not in remote interpretation but in disciplined curiosity: What pattern is recurring? What feeling is being protected against? What role is the counsellor being invited to play? What new experience might make the pattern thinkable and therefore changeable?

## 13. Review and Discussion Questions

**Review and Discussion Questions**

1. Explain unconscious process without using mystical language.
2. Distinguish projection, splitting, and displacement in school examples.
3. Why should defences be understood as protection before pathology?
4. How can countertransference be useful without becoming self-indulgent?
5. Write a tentative interpretation for a student who stops work near completion.
6. What makes a psychodynamic formulation falsifiable enough for ethical practice?
7. When should present safeguarding reality override exploration of meaning?

## 14. Practice Activities

**Practice and Application**

### Activity 47.1 — Pattern map

Map a fictional presenting problem across home, school, peers, and counselling. Identify repeated roles and affects.

### Activity 47.2 — Defence dialogue

Write two counsellor responses to intellectualisation: one confrontational and one function-respecting. Compare likely effects.

### Activity 47.3 — Rupture repair

Draft a repair statement after a counsellor arrives ten minutes late to meet a young person with abandonment fears.

## 15. Annotated Reading Pathways

**For clinical foundations.** Lemma provides a rigorous contemporary introduction without requiring allegiance to one school.

**For development.** Winnicott, Bion, and attachment research illuminate containment, play, and relational learning.

**For adolescents.** Read psychodynamic theory alongside mentalization, family systems, and trauma-informed practice so that internal formulation remains connected to present relationships and environments.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Psychodynamic and Object Relations Approaches** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is the relational substrate of personality, transference, and developmental lines of interpretation. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is development, agency, identity, culture, relationships, motivation, and ecological resources. The mechanism to keep in view is how beliefs, social models, environments, power, belonging, and developmental timing interact to support or restrict change. The characteristic professional risk is individualising structural harm, stereotyping culture, or demanding resilience while leaving unsafe conditions unchanged. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in schools, families, peer contexts, community services, and culturally responsive practice, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete

categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Ines is fifteen and is seen in a school counselling service for shame after academic failure. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Ines's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Ines explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the

visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on development, agency, identity, culture, relationships, motivation, and ecological resources. The first intervention is deliberately modest. Ines chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Ines has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Ines can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.

- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Psychodynamic and Object Relations Approaches

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Psychodynamic and Object Relations Approaches** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

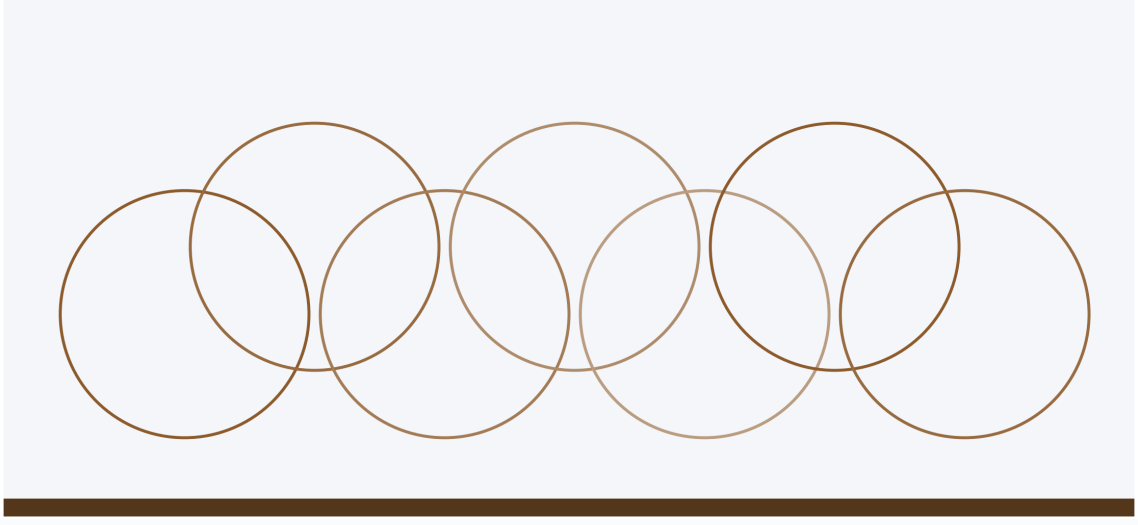
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Psychodynamic and**

**Object Relations Approaches** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Psychodynamic and Object Relations Approaches**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

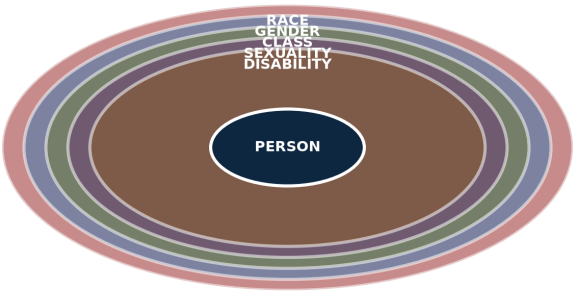
**Written consolidation.** In 250 words, explain Psychodynamic and Object Relations Approaches to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 48

# Multicultural, Feminist, and Intersectional Theory

Power, voice, and privilege in the counseling relationship and in the theories that inform it.

## Learning Objectives



By the end of this chapter, the student should be able to:

- Explain why culture is not an optional variable added after theory but a context that shapes distress, identity, help seeking, and therapeutic power.
- Describe multicultural counselling competencies and cultural humility.
- Explain feminist theory's attention to power, gender, socialisation, and empowerment.
- Define intersectionality and apply it without reducing a young person to a list of categories.
- Use cultural formulation and broaching in assessment.
- Recognise cultural bias in diagnosis, testing, school discipline, and theory selection.
- Practise anti-oppressive, culturally sustaining counselling with children, adolescents, families, and institutions.

## Chapter Overview

Every counselling theory carries assumptions about what a person is, what a family should look like, what emotions mean, what counts as maturity, and who has authority to define a problem. Multicultural, feminist, and intersectional theories make those assumptions visible. They ask not only “What is happening inside this young person?” but also “What has happened around them, what meanings are available to them, whose knowledge is being trusted, and what power does the counsellor hold?”

**Intersecting Systems of Privilege and Oppression**

*Oppression is not additive but multiplicative: each system alters the meaning of the others.*

**Figure 48.38** Intersectionality: overlapping social identities and systems of power shape experience in ways that cannot be understood by adding categories separately.

## 1. Culture as Context, Not Decoration

Culture includes ethnicity, race, language, migration, nationality, religion or non-religious worldview where relevant to the client, class, disability culture, gender norms, sexuality, family forms, region, and

institutional cultures such as school or care systems. This textbook avoids faith-based structures, but culturally responsive practice still requires recognising when a client identifies religious or spiritual commitments as personally important, without the counsellor importing religious content or practice.

Cultural competence is not mastery of a catalogue of group traits. That approach produces stereotypes. Contemporary practice emphasises **cultural humility**: lifelong self-critique, recognition of power imbalance, openness to learning from the client, and institutional accountability.

The counsellor asks: What should I understand about your family, community, language, and experiences for this work to be useful? What have services misunderstood before? Who should be involved? What would respect look like here?

## 2. Multicultural Counselling Theory

Multicultural counselling developed as scholars and practitioners challenged the assumption that theories derived from Western, educated, individualist populations were universal. Sue and colleagues articulated competencies in awareness, knowledge, and skills; later frameworks added action and advocacy.

Key concerns include:

- **Worldview:** individual versus collective decision-making, direct versus indirect communication, time orientation, emotional expression, and concepts of illness and healing.
- **Identity development:** how young people understand ethnicity, race, culture, migration, language, and belonging across contexts.
- **Acculturation and enculturation:** adaptation to a dominant culture and connection to heritage culture, neither inherently healthy or unhealthy.
- **Discrimination and racial trauma:** repeated invalidation, surveillance, exclusion, and threat can shape stress physiology, identity, school trust, and help seeking.
- **Language access:** assessment through an interpreter requires trained interpretation, confidentiality, and awareness that family members—especially children—should not interpret sensitive material.

## 3. Feminist Theory

Feminist counselling emerged from recognition that psychological distress cannot be separated from gendered power, violence, labour, caregiving, body norms, and social expectations. Its principles include egalitarian relationship, valuing lived experience, demystifying therapy, empowerment, social change, and attention to intersectional identities.

With adolescents, feminist practice asks how gender norms regulate behaviour. Girls may be rewarded for compliance and punished for anger; boys may be shamed for vulnerability and rewarded for dominance; non-binary and transgender young people may face invalidation or danger. But feminist analysis does not assume all girls are passive or all boys are emotionally illiterate. It examines specific social messages and their costs.

Feminist practice also notices adult gender patterns in the room: mothers blamed for family distress, fathers treated as peripheral, female staff expected to absorb emotional labour, or male counsellors presumed unsafe or authoritative. The goal is not to reverse blame but to redistribute responsibility and voice.

## 4. Intersectionality

Intersectionality, developed in Black feminist legal scholarship by Kimberlé Crenshaw, shows how systems such as racism, sexism, class inequality, ableism, homophobia, transphobia, and age hierarchy interact. A disabled Black girl in care, a working-class migrant boy, and an affluent white LGBTQ+ student may all experience "school anxiety", but the mechanisms, risks, resources, and institutional responses differ.

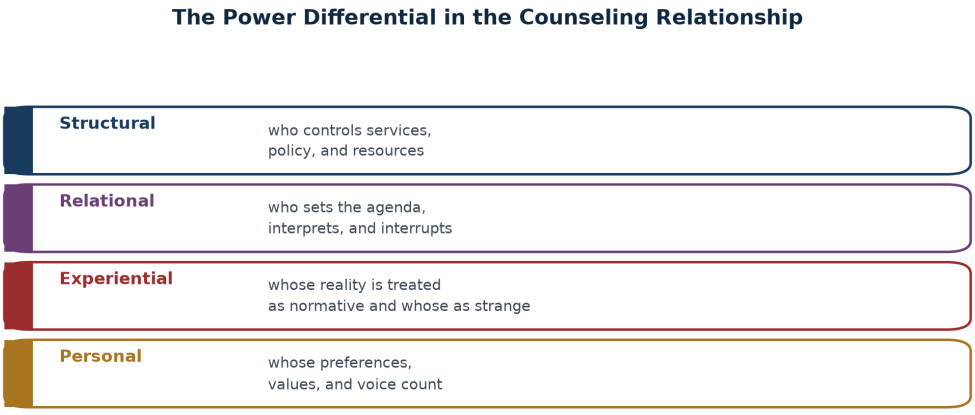


**Figure 48.39** Power differentials in counselling: how professional, adult, institutional, linguistic, and economic power affect voice and choice.

Intersectional practice avoids additive checklists. It asks which identities are salient to the young person, which systems are active in this situation, and where the counsellor's own social position affects perception. It also recognises privilege within marginalised groups and marginalisation within privileged groups.

## 5. Minority Stress and Structural Formulation

Minority stress theory distinguishes distal stressors—discrimination, rejection, victimisation—from proximal processes such as internalised stigma, concealment, and expectation of rejection. Structural formulation extends case conceptualisation to housing, income, transport, school policy, policing, immigration status, health access, language, and disability access.

This matters because a counsellor can otherwise teach coping for conditions that should be changed. Breathing exercises do not remedy racist discipline. Self-esteem work does not replace accessible toilets, interpreters, safe transport, or anti-bullying enforcement. Culturally responsive counselling therefore includes advocacy and consultation.

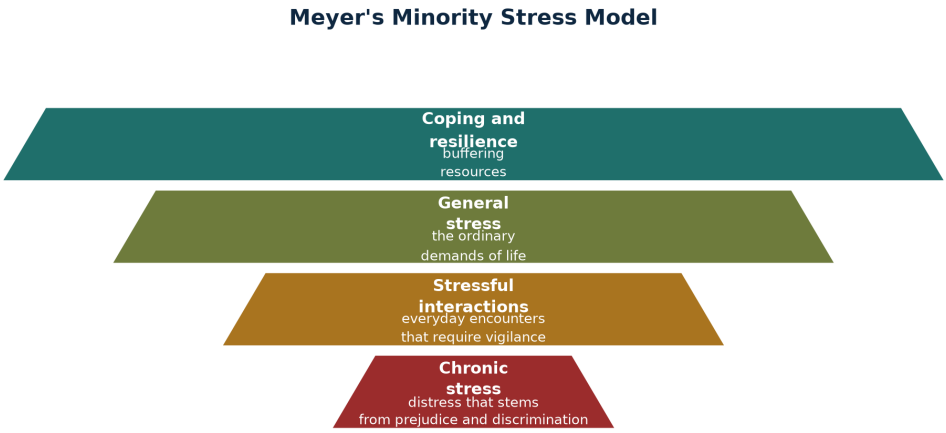

**Figure 48.40** Minority stress processes linking social stigma and discrimination to vigilance, concealment, internalised stigma, and health outcomes.

## 7. Broaching and Cultural Formulation

Broaching is the counsellor's intentional invitation to discuss culture, identity, power, and difference. Silence does not create neutrality; it often tells the young person that these topics are unsafe or irrelevant.

A developmentally appropriate broach might be: “People's experiences at school can be affected by race, language, disability, gender, family income, or being new to a place. I don't want to assume which, if any, matter for you. Are any of those part of what you're dealing with?”

Cultural formulation explores:

- the young person's and family's explanation of the problem;
- salient identities and communities;

- migration, language, and intergenerational differences;
- discrimination and institutional experiences;
- family roles, authority, privacy, and decision-making;
- strengths, cultural resources, and trusted helpers;
- differences between client and counsellor;
- barriers to services and previous experiences of help.

The DSM-5 Cultural Formulation Interview provides useful prompts, though it should be adapted for adolescents and not treated as an interrogation.

## 8. Assessment, Diagnosis, and Testing

Cultural bias can enter through language, norms, item content, examiner behaviour, and interpretation. A quiet adolescent may be respectful, frightened, dissociating, neurodivergent, unfamiliar with the language of assessment, or uninterested. A parent who challenges a professional may be advocating within a system that has previously ignored them.

Before diagnosing, ask whether behaviour is developmentally expected, culturally congruent, situationally adaptive, or produced by unmet access needs. Use multiple informants and settings, validated translations, interpreters, and dynamic assessment where appropriate. Document uncertainty.

School data require disaggregation and scepticism. If one group receives more exclusions, restraint, lower grades for similar work, or fewer referrals to support, individual counselling cannot be the sole response. The institution becomes part of the formulation.

## 9. Case Illustration: “Defiant” in Two Languages

**Presentation.** Samira, fourteen, recently arrived in a new country, is referred for refusing to speak in class and arguing with her mother at home. School staff suggest selective mutism and oppositional behaviour.

**Cultural formulation.** Samira speaks three languages but is still acquiring academic English. In class she fears pronunciation errors after students imitated her accent. At home she interprets for her mother at appointments, giving her adult responsibility but little authority. Her mother, once a pharmacist, works nights cleaning and feels grief and status loss. Arguments occur when Samira refuses further interpreting for complex medical letters.

**Intersectional reading.** Gender, migration, language, class change, age, and parentification interact. Samira is simultaneously privileged by adults as competent and burdened by that competence. Her silence protects dignity at school; her anger at home protests an unsustainable role.

**Intervention.** The school provides language support, private ways to answer, anti-bullying action, and a bilingual staff contact. The service uses professional interpreters and translated letters so Samira is not the family's administrative bridge. Counselling validates grief and status changes, helps mother and daughter negotiate interpreting boundaries, and builds Samira's confidence through small speaking successes. The counsellor does not diagnose defiance from behaviour that had communicative and structural logic.

## 10. Feminist and Anti-Oppressive Practice in Sessions

Practical commitments include:

- explain counsellor power, records, confidentiality, and choices in accessible language;
- invite correction and treat disagreement as information;
- avoid mother blaming and include fathers, kin, and chosen supports where safe;
- notice whose time, body, privacy, and labour are expected to adjust;
- make goals with the young person, not merely for institutional convenience;
- use interpreters and accessible formats;
- challenge discriminatory policies through consultation and governance;
- evaluate outcomes by client-defined wellbeing and participation, not compliance alone.

Self-reflection must lead somewhere. A counsellor who recognises bias but continues using the same referral thresholds, language, and punitive partnerships has insight without action.

## 11. Evidence and Limitations

Evidence supports culturally adapted interventions for some populations and outcomes, though adaptation is heterogeneous. Cultural humility is associated with stronger alliance and client perceptions of counsellor competence. Feminist and empowerment-oriented approaches have supportive but variable evidence depending on population and outcome.

No competency framework can guarantee responsive practice. Training can become performative if institutions do not change staffing, language access, data monitoring, discipline patterns, and decision-making power. Intersectionality can also be diluted into a slogan. Its test is whether formulation and action change.

## 12. Key Terms

**Key Terms at a Glance**

- **Cultural humility** — Lifelong self-critique, openness, and accountability in cross-cultural relationships.
- **Broaching** — Intentionally inviting discussion of culture, identity, difference, and power.
- **Intersectionality** — Analysis of interacting social identities and systems of power.
- **Minority stress** — Stress arising from stigma, discrimination, concealment, and expectation of rejection.
- **Structural formulation** — Case conceptualisation that includes material and institutional conditions.
- **Parentification** — A child assuming adult practical or emotional responsibilities.
- **Anti-oppressive practice** — Counselling that identifies and acts against power relations producing harm.

## 13. Chapter Summary

Multicultural, feminist, and intersectional theories change the counsellor's questions. Distress is still personal, but never only personal. Identity, language, power, discrimination, family roles, and institutional design shape both suffering and recovery. Ethical practice therefore combines humility in the room with action beyond it.

## 14. Review and Discussion Questions

**Review and Discussion Questions**

1. Why is cultural competence as a trait checklist inadequate?
2. Write two appropriate broaching statements for adolescents.
3. Apply intersectionality to school exclusion without making an additive list.
4. How does feminist theory alter mother blaming in family work?
5. Distinguish cultural formulation from stereotyping.
6. Identify three points where assessment bias can enter.
7. When does coping work become ethically insufficient without advocacy?

## 15. Practice Activities

**Practice and Application**

### Activity 48.1 — Assumption audit

Take a familiar theory from this book and list its assumptions about selfhood, family, emotion, communication, and maturity.

### Activity 48.2 — Structural formulation

Rewrite a fictional case formulation twice: once individual-only and once including language, income, school policy, disability access, and discrimination.

### Activity 48.3 — Institutional data

Design three questions a school counselling service should ask of its referral, exclusion, and outcome data to detect inequity.

## 16. Annotated Reading Pathways

**For competencies.** Sue and colleagues and the Multicultural and Social Justice Counseling Competencies provide frameworks, but read them alongside cultural humility research.

**For intersectionality.** Begin with Crenshaw and Black feminist scholarship rather than secondary summaries alone.

**For practice.** Combine cultural formulation with school consultation, interpreter-mediated therapy, disability justice, and anti-racist organisational change.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Multicultural, Feminist, and Intersectional Theory** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is power, voice, and privilege in the counseling relationship and in the theories that inform it. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is development, agency, identity, culture, relationships, motivation, and ecological resources. The mechanism to keep in view is how beliefs, social models, environments, power, belonging, and developmental timing interact to support or restrict change. The characteristic professional risk is individualising structural harm, stereotyping culture, or demanding resilience while leaving unsafe conditions unchanged. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in schools, families, peer contexts, community services, and culturally responsive practice, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete

categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Kofi is fifteen and is seen in a community adolescent clinic for school avoidance and rising panic. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Kofi's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Kofi explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the

visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on development, agency, identity, culture, relationships, motivation, and ecological resources. The first intervention is deliberately modest. Kofi chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Kofi has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Kofi can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.

- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Multicultural, Feminist, and Intersectional Theory

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Multicultural, Feminist, and Intersectional Theory** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

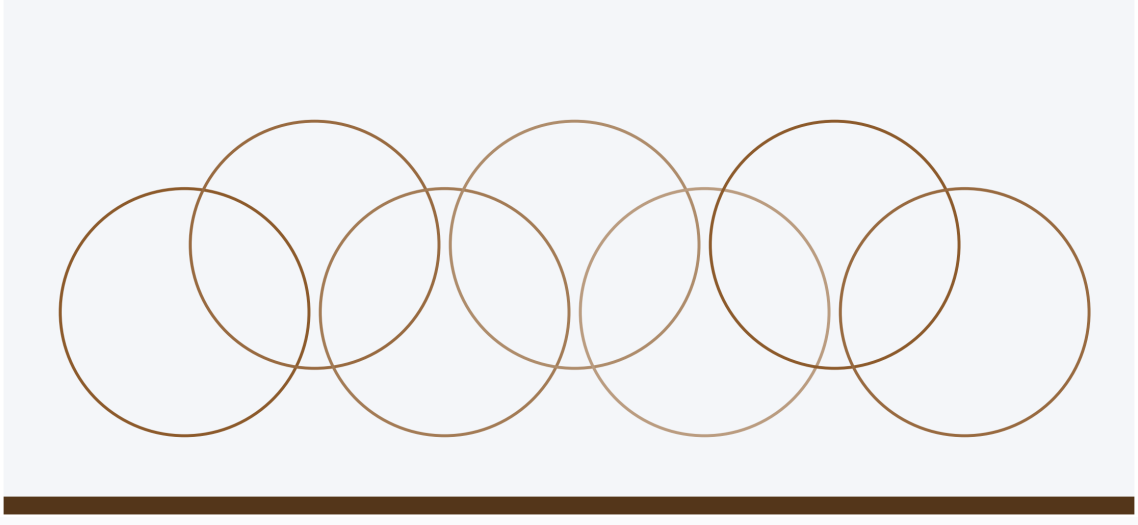
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Multicultural,**

**Feminist, and Intersectional Theory** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Multicultural, Feminist, and Intersectional Theory**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Multicultural, Feminist, and Intersectional Theory to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 49

# Affirmative Practice with LGBTQ+ Youth

Gender-responsive and affirming practice, the role of the therapeutic alliance, and the harms of conversion practices.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Use respectful, developmentally appropriate language about sexual orientation, gender identity, gender expression, and sex characteristics.
- Explain minority stress, family acceptance, school safety, and identity development.
- Distinguish affirmation from pressure to label, disclose, or transition in any direction.
- Conduct risk, safety, family, and school assessments without making identity itself the pathology.
- Develop confidentiality and disclosure plans with LGBTQ+ adolescents.
- Respond ethically to family rejection, bullying, conversion efforts, and institutional discrimination.
- Evaluate evidence and legal variation while maintaining professional standards of dignity and safety.

## Chapter Overview

Affirmative practice begins from a clear professional position: lesbian, gay, bisexual, transgender, queer, questioning, intersex, asexual, and other sexual and gender minority identities are variations of human experience, not mental disorders. Distress commonly arises from stigma, rejection, bullying, concealment, unsafe environments, and barriers to care. The counsellor's task is not to steer a young person toward or away from an identity, but to support safety, exploration, self-understanding, family communication where safe, and access to appropriate resources.

Adolescents may use labels, reject labels, change labels, or hold uncertainty. Developmentally responsive practice follows the young person's language while keeping conversation open. A label can provide community and coherence; it can also feel constraining. Neither certainty nor questioning requires correction.

## 1. Language and Concepts

**Sexual orientation** concerns patterns of romantic, emotional, and/or sexual attraction. **Gender identity** is a person's internal sense of gender. **Gender expression** includes clothing, voice, mannerisms, name, and presentation. **Sex assigned at birth** is a classification made from observed characteristics and is not identical to gender identity. **Intersex** refers to variations in sex characteristics. **Cisgender** describes people whose gender identity aligns with sex assigned at birth; **transgender** describes those whose identity differs. **Non-binary** is an umbrella term for identities not exclusively man or woman.

Names and pronouns matter. Ask privately what name and pronouns the young person uses in different settings. A name used with friends may not be safe at home or school. Record systems can unintentionally disclose information; practitioners must know what appears on letters, registers, appointment texts, and shared records.

Sexual orientation and gender identity are not phases to be diagnosed by adults. Exploration is normal, and so is early certainty. Some young people know from childhood; others understand themselves later. Neither timeline is more authentic.

## 2. Minority Stress and Resilience

Minority stress includes bullying, slurs, exclusion, family rejection, discriminatory policies, online harassment, expectation of rejection, concealment, and internalised stigma. These stressors help explain disparities in depression, anxiety, self-harm, suicide risk, substance use, homelessness, and school disengagement. Disparity is not destiny, and group statistics must never be used to presume an individual's experience.

Resilience is equally important. LGBTQ+ youth build chosen families, friendships, creative communities, online support, humour, activism, and pride. Affirmative counselling identifies resources without romanticising adversity. A young person should not have to become exceptionally resilient because adults refuse to make environments safe.

Family acceptance is a major protective factor. Research associated with the Family Acceptance Project links specific accepting behaviours—listening, advocating, welcoming friends, supporting expression, connecting with resources—to better health outcomes. Rejection behaviours—blocking access to LGBTQ+ friends, blaming the young person for bullying, forcing concealment, or using identity as an insult—are associated with poorer outcomes.

School belonging matters. Inclusive curricula, anti-bullying enforcement, gender-neutral facilities where available, supportive staff, student clubs where lawful and safe, and protection from forced outing can alter daily stress more powerfully than weekly counselling alone.

## 3. Identity Development without a Script

Older stage models proposed linear movement from confusion to pride and synthesis. Contemporary practice treats identity development as fluid, contextual, and sometimes non-linear. A young person may be out to friends but not family, use one name online and another at school, or identify differently across time.

Exploration may involve clothing, names, pronouns, dating, community, media, language, and imagination. The counsellor should distinguish exploration from risk behaviour. Trying a new name is not equivalent to unsafe sexual activity; attending a pride event is not pathology; asking questions about bodies requires accurate information and safeguarding, not shame.

Assessment asks:

- What words, if any, feel right now?
- Where is it safe or unsafe to be known?
- Who knows, who does not, and who controls disclosure?
- What support exists?
- What stress is linked to identity, and what is unrelated?
- What does the young person want from counselling?

## 4. Risk and Safety Assessment

Risk assessment should be specific and non-sensational. Ask about suicidal thoughts, self-harm, bullying, sexual exploitation, violence, running away, homelessness, substance use, eating concerns, and access to

support. Do not assume identity causes risk; identify mechanisms and contexts.

Safety planning includes trusted adults, safe routes, online privacy, emergency contacts, school staff, community organisations, and what to do if outed. Digital safety requires attention to shared devices, location tracking, screenshots, cloud backups, and messages that may be discovered.

Conversion efforts—practices intended to change sexual orientation or gender identity—lack credible evidence of effectiveness and are associated with harm. They are prohibited or restricted in many jurisdictions and opposed by major professional bodies. Counsellors must not provide, refer to, or disguise such practices as neutral exploration. Ethical exploration supports the young person's self-understanding without a predetermined identity outcome.

## 6. Confidentiality, Names, and Disclosure

Confidentiality can be a safety intervention. Before counselling begins, explain limits in plain language and identify exactly what may be shared with parents, school staff, health providers, and safeguarding services. Distinguish safety information from identity information. A parent may need to know that a young person is self-harming without being told every detail of sexuality or gender exploration, subject to law and risk.

Disclosure planning asks:

1. What might be gained and risked by telling each person?
2. What is the likely response, based on evidence rather than hope alone?
3. What timing, setting, and medium are safest?
4. Who can be present or nearby?
5. What housing, financial, educational, and emotional supports exist if the response is poor?
6. What boundaries will the young person set about questions and further disclosure?

The counsellor does not pressure coming out as a marker of therapeutic progress. Concealment can be costly, but it can also be protective. The ethical goal is controlled, informed choice where possible.

Records require special care. Use chosen name and pronouns in the therapeutic record where systems allow, note context-specific names, and avoid unnecessary recording of sensitive details. Appointment reminders and school registers can out a student. Practitioners should advocate for record systems that protect privacy and dignity.

## 7. Family Work

Family responses range from celebration to grief, confusion, anger, fear, or rejection. Initial shock is not always final rejection. Parents may need space to ask questions without making the young person responsible for educating or comforting them.

Family sessions should not become debates about the legitimacy of the young person's identity. Ground rules can include respectful names and pronouns, no insults, no threats, no forced disclosure to extended family, and pauses when conversation escalates. Separate parent sessions may help adults process fears, obtain accurate information, and identify concrete accepting behaviours.

Concrete acceptance includes listening without immediate correction, defending the young person against bullying, welcoming friends, supporting safe expression at home, using the chosen name where agreed, and helping access supportive communities. Where family behaviour creates danger, safeguarding and alternative support take precedence over preserving a joint format.

Cultural and religious contexts require respectful complexity. This textbook does not use faith-based structures, and counsellors should not impose theological arguments. They can, however, help families distinguish their values and fears from immediate safety behaviours: even where beliefs differ, violence, expulsion, humiliation, and withdrawal of care cause harm. Referral to culturally congruent family resources may help when chosen by the family.

## 8. School Practice

School counsellors can assess bullying patterns, staff responses, facilities, dress codes, sports access, curriculum inclusion, and confidentiality in registers and communications. Interventions may include safety routes, trusted staff, timetable adjustments, anti-bullying action, peer bystander work, and advocacy.

Do not make the targeted student responsible for educating the whole school or repeatedly recounting harm. Incident systems should record patterns, locations, and adult responses. Restorative approaches are inappropriate where they force contact with an unsafe perpetrator or minimise identity-based harassment.

Clubs and peer groups can be protective where they are permitted and safely facilitated. If a club would expose students to danger, alternatives may include off-site youth services, moderated online communities with safeguarding, library resources, and individual mentoring.

## 9. Health and Specialist Referral

Counsellors should know local pathways for sexual health, HIV prevention and care, substance use, eating disorders, trauma, housing, and gender-related health care. Gender care for minors is regulated differently across jurisdictions and may involve specialist multidisciplinary assessment. The counsellor's role is supportive, non-directive regarding identity outcome, accurate about local process, and attentive to distress,

family communication, school safety, and co-occurring needs while referrals proceed.

Avoid acting as gatekeeper beyond professional competence. Do not require a young person to prove identity through stereotypes. Do not delay mental health support while specialist assessment is pending. Coordinate with consent and document who holds responsibility for each part of care.

## 10. Case Illustration: Two Names, One Safety Plan

**Presentation.** Alex, fifteen, uses the name Alex and they/them pronouns with friends. At home and school, records use a different name. Alex has begun skipping lunch to avoid a changing-room corridor where students shout slurs. Their mother has requested counselling because Alex is “secretive and angry”.

**Assessment.** Alex is not depressed about being non-binary; they are exhausted by vigilance and by correcting adults. Home response is uncertain. An older sibling is supportive. Alex fears a school letter will reveal the chosen name.

**Intervention.** The counsellor first addresses administrative safety: appointment messages go to Alex's phone, not a shared family account; the counsellor checks what name appears on school sign-in sheets. Together they identify a trusted teacher and an alternative lunch space that does not isolate Alex from friends.

Disclosure is planned in stages. Alex tells their mother with the sibling nearby at home, after preparing answers and an exit plan to the sibling's room. The counsellor holds a separate parent session focused on immediate behaviours: listen, use Alex at home if Alex confirms, do not inform extended family, and challenge corridor bullying narratives that blame Alex's expression.

School action targets location and supervision rather than requiring Alex to report every incident publicly. Over time, Alex eats with friends again. Family conversations remain imperfect, but the mother practises the chosen name and stops threatening to remove internet access as a response to identity. The outcome is not framed as Alex becoming more resilient to harassment; adults reduce exposure and increase support.

## 11. Evidence and Limitations

Research consistently associates family acceptance, school belonging, supportive policies, and access to affirming communities with better mental health among LGBTQ+ youth. Interventions that reduce bullying and rejection operate at plausible causal pathways, though many studies are observational and contexts vary.

Evidence for specific counselling models designed solely for LGBTQ+ adolescents is still developing. Affirmative adaptations of cognitive-behavioural and family interventions show promise. Practitioners should monitor outcomes rather than assume affirmation as an attitude guarantees effective technique.

Legal and policy environments vary and can change. Students must learn local law on consent, confidentiality, safeguarding, education, health referrals, and discrimination, while recognising that professional ethics may require advocacy where law or institutional practice creates avoidable harm.

## 12. Key Terms

**Key Terms at a Glance**

- **Affirmative practice** — Care that validates sexual and gender diversity and addresses stigma-related stress without pathologising identity.
- **Chosen name** — The name a young person uses for themselves, which may vary by safety context.
- **Outing** — Disclosing someone's sexual orientation or gender identity without consent.
- **Family acceptance** — Concrete behaviours that communicate support, protection, and belonging.
- **Conversion efforts** — Practices intended to change sexual orientation or gender identity; unsupported and associated with harm.
- **Chosen family** — Supportive relationships formed beyond biological or legal family.
- **Minority stress** — Stress produced by stigma, discrimination, vigilance, concealment, and internalised negativity.

## 13. Chapter Summary

Affirmative practice is neither neutral about harm nor prescriptive about identity. It protects confidentiality, follows the young person's language, reduces environmental danger, builds family acceptance where possible, and treats resilience as something communities can support rather than demand. The counsellor's credibility rests on small administrative details as much as large statements: the right name, a safe message, a private record, a teacher who intervenes, and a door that does not have to be explained every day.

## 14. Review and Discussion Questions

**Review and Discussion Questions**

1. Distinguish sexual orientation, gender identity, gender expression, and sex assigned at birth.
2. Why is coming out not automatically a therapeutic goal?
3. List five concrete family acceptance behaviours.
4. How can ordinary record systems create risk?
5. Why are conversion efforts ethically unacceptable?
6. Design a school safety response that does not burden the targeted student.
7. What should a counsellor do while a young person awaits specialist gender-related assessment?

## 15. Practice Activities

**Practice and Application**

### Activity 49.1 — Context map

Create a fictional adolescent's map of home, school, friends, online spaces, and services. Record name, pronouns, outness, support, and risk for each context.

### Activity 49.2 — Disclosure plan

Write a staged disclosure plan that includes timing, support person, likely responses, boundaries, and contingency housing or transport.

### Activity 49.3 — Administrative audit

Audit a fictional counselling service's forms, reminders, waiting-room procedures, and school reports for accidental outing risks.

## 16. Annotated Reading Pathways

**For guidelines.** APA guidelines provide detailed competencies for sexual minority and transgender and gender nonconforming practice.

**For family work.** Family Acceptance Project materials translate research into specific caregiver behaviours.

**For schools.** GLSEN and comparable school climate research show how policy, staff intervention, facilities, and peer belonging shape daily safety.

**For local practice.** Learn current regional law and reputable youth, housing, sexual health, and crisis services before referrals are needed.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Affirmative Practice with LGBTQ+ Youth** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is gender-responsive and affirming practice, the role of the therapeutic alliance, and the harms of conversion practices. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is development, agency, identity, culture, relationships, motivation, and ecological resources. The mechanism to keep in view is how beliefs, social models, environments, power, belonging, and developmental timing interact to support or restrict change. The characteristic professional risk is individualising structural harm, stereotyping culture, or demanding resilience while leaving unsafe conditions unchanged. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements;

others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in schools, families, peer contexts, community services, and culturally responsive practice, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable,

and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Amara is fifteen and is seen in a family support service for repeated classroom escalation. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Amara's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Amara explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through

repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on development, agency, identity, culture, relationships, motivation, and ecological resources. The first intervention is deliberately modest. Amara chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Amara has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Amara can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.

- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Affirmative Practice with LGBTQ+ Youth

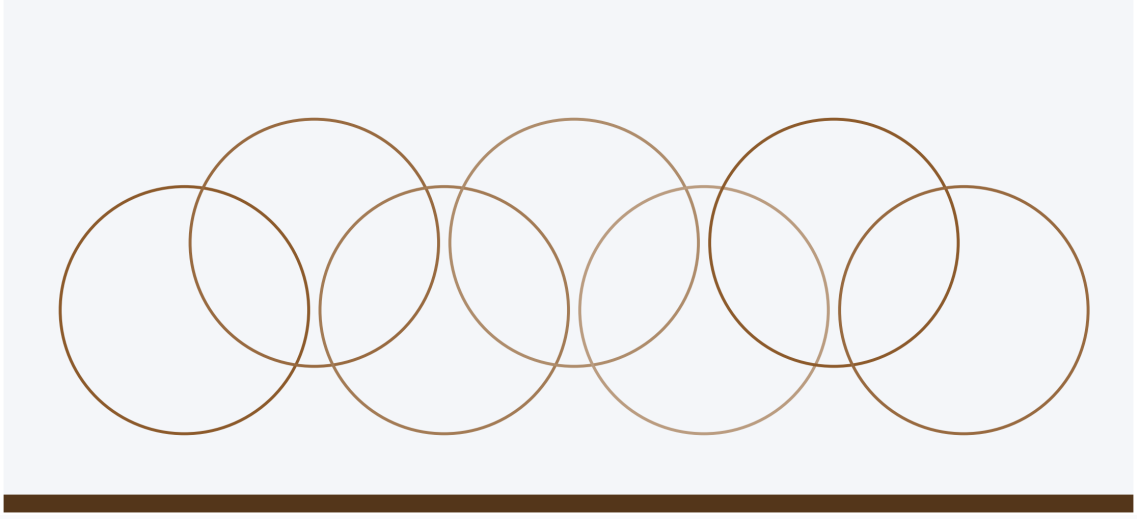
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Affirmative Practice with LGBTQ+ Youth** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Affirmative Practice with LGBTQ+ Youth** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Affirmative Practice with LGBTQ+ Youth**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Affirmative Practice with LGBTQ+ Youth to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 50

# Resilience, Ecological Systems, and Strengths-Based Practice

Bronfenbrenner, Masten's resilience research, and the systematic mobilisation of protective factors.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Define resilience as a dynamic process rather than a personality trait.
- Describe Bronfenbrenner's ecological systems and their relevance to case formulation.
- Identify individual, relational, school, community, and cultural protective processes.
- Explain risk, protective, promotive, and compensatory factors.
- Use strengths-based assessment without denying adversity or transferring responsibility to the young person.
- Design multi-level interventions for individuals, families, schools, and communities.
- Evaluate evidence, cultural considerations, and ethical risks.

## Chapter Overview

Resilience is often misunderstood as toughness: the child who “bounces back”, copes without complaint, and asks little from adults. That definition is both scientifically wrong and ethically dangerous. Resilience is better understood as the capacity of a developing system—child, family, school, community—to adapt successfully under adversity. It depends on relationships, resources, opportunities, biology, culture, and timing. A young person may function well academically while struggling emotionally, cope at home but not at school, or deteriorate when a single key support is removed.

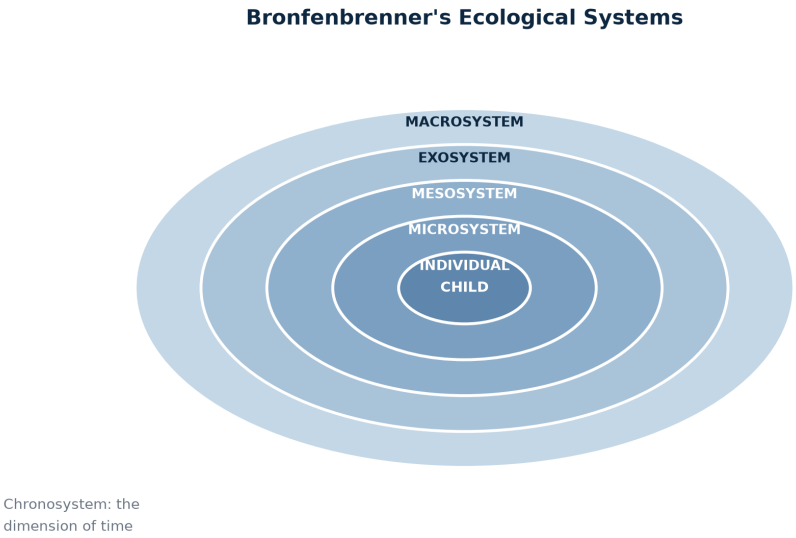


**Figure 50.41** Ecological systems: the developing young person nested within family, school, peer, community, cultural, policy, and time contexts.

## 1. Ecological Systems Theory

Bronfenbrenner's model places development within interacting contexts.

**Microsystem:** immediate settings such as family, classroom, peer group, team, and online community.

**Mesosystem:** connections among microsystems—for example, whether school and family communicate respectfully, or whether a youth service and health clinic coordinate.

**Exosystem:** settings that affect the young person indirectly, including parental employment, school funding, transport, housing services, and media systems.

**Macrosystem:** cultural values, laws, economic structures, discrimination, and beliefs about childhood, disability, gender, and success.

**Chronosystem:** time and transitions—developmental stage, historical events, migration, bereavement, policy change, and the duration of adversity.

Ecological formulation prevents the counsellor from locating every problem in the nearest person. A student's inattention may involve sleep, classroom noise, hunger, parental shift work, bus routes, medication timing, peer conflict, and an undiagnosed learning difficulty. Each level suggests different interventions and different responsible actors.

## 2. Risk and Protection

A **risk factor** increases probability of poor outcome. A **protective factor** reduces the effect of risk. A **promotive factor** supports positive outcomes across levels of risk. These are probabilistic, not destiny.

Risk accumulates. One stressor may be manageable; poverty, unstable housing, parental illness, school exclusion, discrimination, and bereavement together can overwhelm systems. Timing matters: the same event has different implications at age five, twelve, or seventeen. Duration and controllability matter too.

Protection often comes from ordinary systems—what Ann Masten calls “ordinary magic”. These include:

- at least one stable, committed adult relationship;
- effective caregiving and family organisation;
- cognitive, language, and self-regulation skills;
- school belonging and opportunities for mastery;
- friendships and prosocial peer groups;
- cultural identity, community participation, and meaningful roles;
- safe housing, nutrition, sleep, health care, and transport;
- services that coordinate rather than fragment care.

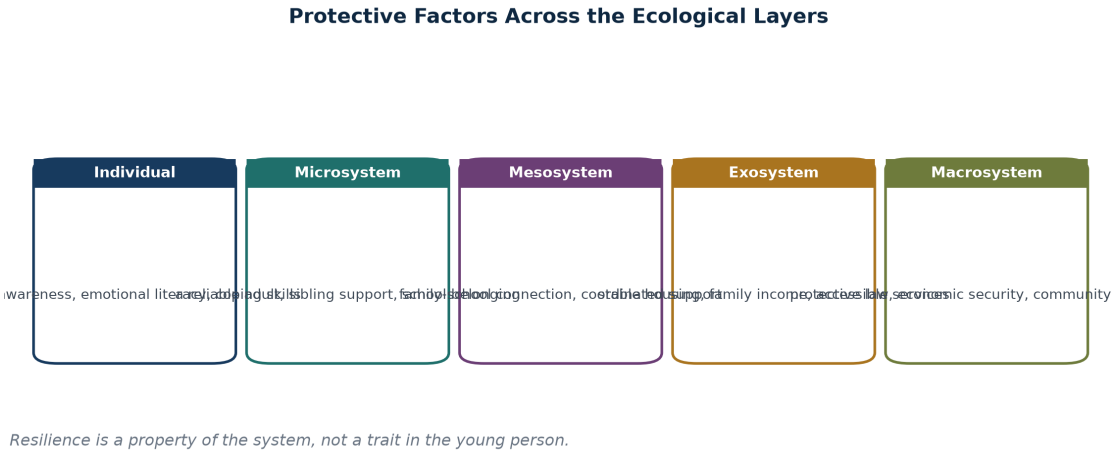

**Figure 50.42** A resilience map showing risk load, protective processes, and intervention points across individual, relational, school, and community systems.

## 3. Resilience as Process

Resilience is not a permanent state. A young person may be resilient in relation to academic performance after bereavement but not in relation to trust. Another may manage chronic illness with remarkable organisation while finding peer rejection destabilising.

Assessment should therefore specify:

1. Resilient in which domain?
2. Under what adversity?
3. Over what period?
4. Supported by which processes?
5. At what hidden cost?

The last question matters. A young person who cares for siblings, suppresses distress, and achieves highly may be praised as resilient while experiencing exhaustion, loneliness, or delayed developmental opportunities. Adults should not use resilience language to justify withholding help.

## 4. Strengths-Based Practice

Strengths-based practice begins by identifying capacities, interests, relationships, cultural resources, previous coping, values, and hopes. It asks what has survived, what matters, who helps, and what a good-enough future would look like.

It is not positive thinking. It does not require reframing abuse as growth, poverty as character-building, or discrimination as an opportunity. Strengths are resources for action, not excuses for institutions.

Good strengths assessment is specific. “She is resilient” is weak. “She maintains friendships, notices when her younger brother is overwhelmed, uses music to regulate, attends regularly when transport is available, and trusts one teacher” is usable. Each strength suggests an intervention pathway.

## 5. Developmental Cascades

Small changes can cascade. Improved sleep improves attention; attention improves teacher feedback; feedback improves academic efficacy; efficacy increases attendance; attendance expands friendships. Negative cascades also occur: exclusion reduces learning, peer contact, family income through parental work absence, and trust in institutions.

Ecological practice searches for high-leverage points where modest, feasible change can start a positive cascade. Sometimes the best counselling intervention is a bus pass, a timetable adjustment, a hearing assessment, a parent work-schedule letter, or repair of one teacher relationship.

## 7. Ecological Assessment

An ecological assessment can be organised as a visual map with the young person at the centre and rings for family, peers, school, services, community, culture, policy, and time.

For each ring, ask:

- What pressures operate here?
- What resources operate here?
- Who has power?
- What relationship connects this ring to the others?
- What can be changed, by whom, and how quickly?
- What must be endured safely while longer change is pursued?

The map should include online environments and informal supports: extended kin, neighbours, coaches, faith-neutral community groups where relevant, youth workers, cultural organisations, libraries, and safe public spaces.

Assessment also examines service ecology. Multiple professionals may each hold a partial plan. The young person repeats their story, receives contradictory advice, and attends appointments that conflict with school. Coordination is a clinical intervention.

# 8. Multi-Level Intervention

## Individual level

Skills, therapy, health care, sleep, learning support, assistive technology, and opportunities for mastery.

## Relational level

Parent coaching, family communication, mentoring, peer mediation where safe, restorative conversations, and repair with teachers.

## School level

Belonging, accessible curriculum, anti-bullying systems, fair discipline, staff training, flexible pathways, and student voice.

## Community level

Youth provision, sport, arts, libraries, safe transport, volunteering, employment experience, and culturally specific resources.

## Policy and institutional level

Housing, income support, disability access, interpreter services, exclusion reform, health access, and data monitoring for inequity.

The counsellor need not personally deliver every intervention. Professional competence includes referral, consultation, advocacy, letter writing, meeting facilitation, and follow-through.

# 9. Case Illustration: The “Resilient” Young Carer

**Presentation.** Ruth, sixteen, is praised by school for excellent attendance and care of her younger brother, who has complex medical needs. She asks for counselling because she has stopped applying to sixth-form courses and cries on the bus.

**Ecological formulation.** Ruth's strengths are real: organisation, empathy, academic ability, and a trusted aunt. The costs are also real. She administers medication before school, translates medical information, sleeps lightly in case her brother needs help, and has no unstructured peer time. Her mother works nights and is exhausted. A school attendance award has unintentionally become pressure never to be ill or late.

**Intervention.** The counsellor resists congratulating Ruth into further endurance. A care assessment is requested; respite and a young-carers service are explored; the hospital provides an adult interpreter and written care plan so Ruth is not the clinical intermediary. School offers a later start after hospital nights and a private route to report absence. Ruth joins a weekly art group protected from caring duties. Her mother and aunt create an emergency rota so Ruth is not the default responder.

Ruth applies to sixth form. The change is not that she becomes more resilient. The ecology becomes less dependent on extracting resilience from her.

## 10. School and Community Applications

Schools can build resilience by ensuring every student has at least one known trusted adult, predictable routines, fair discipline, accessible challenge, extracurricular belonging, anti-bullying enforcement, and early practical help. Universal provision matters because targeted programmes can stigmatise and miss students whose adversity is hidden.

Community resilience requires investment before crisis. Libraries, youth clubs, safe parks, transport, sports, arts, and culturally led organisations are mental health infrastructure even when not labelled as such. Counsellors should know local assets and help young people enter them, including addressing cost, travel, disability access, and fear of being an outsider.

## 11. Evidence and Limitations

Longitudinal research consistently identifies supportive relationships, effective caregiving, self-regulation, school engagement, and community resources as predictors of better adaptation under adversity. Interventions are most credible when they strengthen these ordinary systems.

Resilience research has limitations. Definitions and outcomes vary; many studies are observational; and positive adaptation in one domain may conceal distress in another. Cultural meanings of success differ: independence, academic achievement, family contribution, spiritual life, and collective wellbeing may be weighted differently, though this textbook does not prescribe faith-based goals.

The central ethical limitation is political. Resilience language can shift responsibility from institutions to children. The discipline is to pair every individual strength with an environmental question: What support makes this strength sustainable? What burden should adults remove?

## 12. Key Terms

**Key Terms at a Glance**

- **Resilience** — Successful adaptation under adversity through interacting individual and environmental processes.
- **Microsystem** — Immediate settings in which a young person directly participates.
- **Mesosystem** — Connections among microsystems, such as family–school communication.
- **Exosystem** — Indirect settings affecting development, such as parental employment conditions.
- **Macrosystem** — Cultural, legal, and economic structures shaping development.
- **Chronosystem** — The dimension of time, transitions, and historical context.
- **Promotive factor** — A resource associated with positive outcomes across risk levels.
- **Developmental cascade** — Spreading effects of change across domains and time.

## 13. Chapter Summary

Ecological and strengths-based practice widens the counsellor's field of vision. The young person remains an agent, but not an isolated one. Good practice identifies risk without fatalism, names strengths without exploitation, and intervenes at the level where change is both possible and just.

## 14. Review and Discussion Questions

**Review and Discussion Questions**

1. Why is resilience not a personality trait?
2. Apply all five ecological systems to school refusal.
3. Distinguish risk, protective, and promotive factors.
4. What hidden costs may accompany being labelled resilient?
5. Give three examples of ordinary magic in adolescent development.
6. How can a bus pass or timetable change be a counselling intervention?
7. When does strengths language become unethical?

## 15. Practice Activities

**Practice and Application**

### Activity 50.1 — Ecological map

Construct an ecological map for a fictional young carer, marking pressures, resources, power, and one intervention per level.

### Activity 50.2 — Strength specificity

Rewrite five vague strengths (“resilient”, “mature”, “coping well”) into observable capacities and the supports sustaining them.

### Activity 50.3 — Cascade planning

Identify one small change that could create a positive developmental cascade for a school-avoidant adolescent.

## 16. Annotated Reading Pathways

**For theory.** Bronfenbrenner provides structure; Masten and Ungar provide process and social ecology.

**For practice.** Saleebey's strengths perspective should be read alongside critical literature warning against responsibilising disadvantaged families.

**For schools.** Focus on belonging, trusted adults, fair discipline, practical barriers, and extracurricular access as measurable ecological conditions.

# Practice Laboratory and Extended Worked Example

This laboratory turns **Resilience, Ecological Systems, and Strengths-Based Practice** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is bronfenbrenner, Masten's resilience research, and the systematic mobilisation of protective factors. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is development, agency, identity, culture, relationships, motivation, and ecological resources. The mechanism to keep in view is how beliefs, social models, environments, power, belonging, and developmental timing interact to support or restrict change. The characteristic professional risk is individualising structural harm, stereotyping culture, or demanding resilience while leaving unsafe conditions unchanged. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

## A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in schools, families, peer contexts, community services, and culturally responsive practice, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and**

**eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Jonas is fifteen and is seen in an integrated school and health team for difficulty trusting adults after several service changes. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Jonas's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Jonas explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on development, agency, identity, culture, relationships, motivation, and ecological resources. The first intervention is deliberately modest. Jonas chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Jonas has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Jonas can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Resilience, Ecological Systems, and Strengths-Based Practice

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Resilience, Ecological Systems, and Strengths-Based Practice** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Resilience, Ecological Systems, and Strengths-Based Practice** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

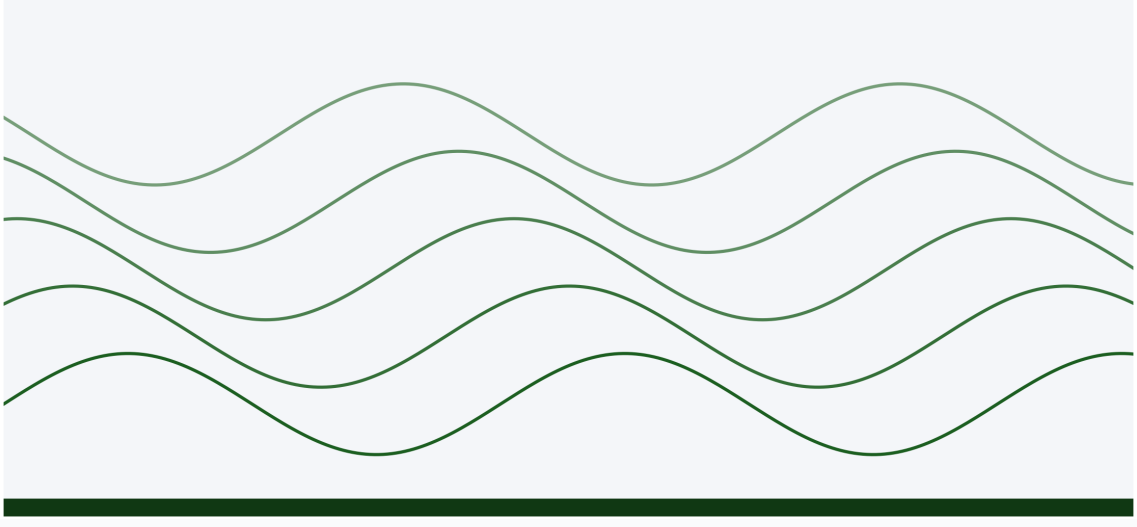
**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Resilience, Ecological Systems, and Strengths-Based Practice**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Resilience, Ecological Systems, and Strengths-Based Practice to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

PART VIII

# Integration, Assessment, and Professional Practice

The working core of the course: how theories are integrated into a coherent stance, how cases are conceptualised, how progress is measured, and how the course itself is taught and assessed.



CHAPTERS IN THIS PART

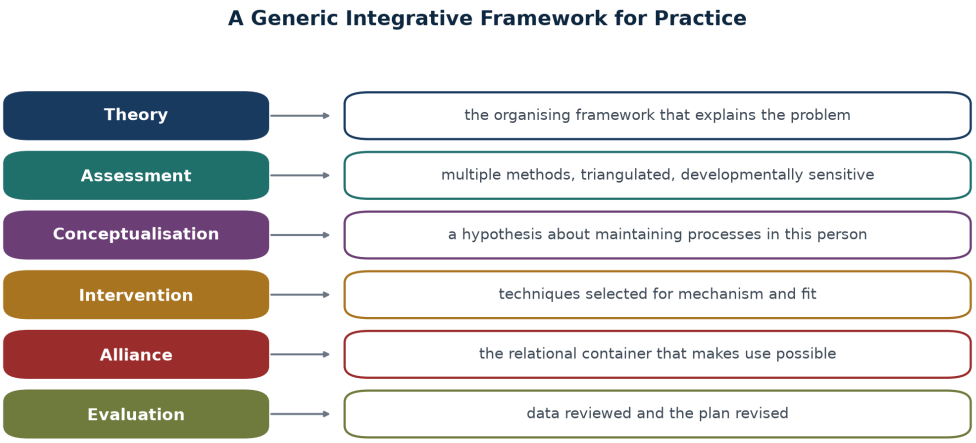
51 Theoretical Integration and the Integrative Stance
52 Case Conceptualization and Treatment Planning
53 Assessment and Outcome Monitoring in Counseling
54 Termination, Evaluation, and the Ethics of Endings
55 Teletherapy and Technology in Counseling with Youth
56 School Counseling Practice and Consultation
57 Teaching CAC. 701: Session Plans and Facilitation
58 Assessment Blueprint, Assignments, and Rubrics

CHAPTER 51

# Theoretical Integration and the Integrative Stance

Technical eclecticism, assimilative integration, and the discipline of a coherent theory of change.

## Learning Objectives



By the end of this chapter, the student should be able to:

- Distinguish theoretical integration, technical eclecticism, common-factors integration, and assimilative integration.
- Evaluate benefits and risks of combining theories.
- Formulate cases across affective, behavioural, cognitive, interpersonal, systemic, developmental, and cultural dimensions.
- Select interventions according to client need, evidence, mechanism, timing, and practitioner competence.
- Maintain coherence when moving between theories during treatment.
- Explain integration to clients and families without presenting a confusing mixture of jargon.
- Use supervision and outcome data to govern integrative choices.

## Chapter Overview

Few experienced counsellors practise one theory in pure form. A practitioner may build a person-centred relationship, use behavioural activation, teach grounding, involve parents, challenge a school practice, and help an adolescent re-author a shame-based story. The question is not whether integration occurs, but whether it is principled.

Unprincipled integration becomes a drawer of techniques: a worksheet because it is Tuesday, a chair exercise because training was recent, a genogram because the family seems complicated. Principled integration begins with formulation. What maintains this problem? What capacity needs building? What relationship or environment must change? What mechanism does each intervention engage? How will we know whether it helps?

*The framework is generic; the content of each row is supplied by the theory the counsellor has chosen to adopt.*

**Figure 51.43** An integrative framework organised around formulation, relationship, mechanisms of change, context, and review.

# 1. Forms of Integration

**Theoretical integration** attempts to combine concepts from two or more theories into a coherent framework. It is intellectually ambitious and difficult because theories disagree about persons, causation, and change.

**Technical eclecticism** selects techniques by evidence and fit without requiring theoretical unification. Its strength is pragmatism; its risk is incoherence.

**Common-factors integration** organises practice around alliance, empathy, expectations, goals, feedback, cultural responsiveness, and therapist effects. It explains why different therapies often produce comparable outcomes but does not by itself specify every technique.

**Assimilative integration** maintains a home theory while importing techniques from others in ways translated into the home framework. A psychodynamic clinician might use behavioural activation as a way to test relational expectations; a CBT clinician might use narrative externalisation to reduce shame before skills work.

# 2. Why Integrate?

Single theories illuminate different levels. Behavioural theory clarifies contingencies. Attachment theory clarifies relational expectations. Cognitive theory clarifies appraisal. Family systems clarify interaction patterns. Trauma theory clarifies state and safety. Cultural theory clarifies power and context.

Adolescent problems rarely sit on one level. School refusal may involve panic physiology, avoidance learning, perfectionistic beliefs, parental accommodation, bullying, sleep disturbance, learning difficulty, and a young person's identity as “the anxious one”. Integration allows sequencing rather than competition.

Integration also respects client preference. Some young people want practical tools; others need to tell a story; many need both at different times. Preference is not the only criterion, but it affects alliance and engagement.

# 3. Risks of Integration

Integration can dilute competence. A practitioner who knows fragments of ten models may deliver none well. It can also conceal contradiction: using unconditional acceptance while covertly engineering compliance; demanding emotional exposure before stabilisation; or asking parents to change while telling the adolescent every problem is systemic.

Other risks include unfalsifiability, technique shopping after setbacks, excessive complexity for the client, and cultural cherry-picking. Integration requires more discipline, not less.

# 4. A Principled Integrative Method

## Step 1: Describe before explaining

Record observable patterns, contexts, strengths, risks, and the client's own language.

## Step 2: Formulate across levels

Use the five-part structure described in Chapter 52: predisposing, precipitating, perpetuating, protective, and presentational factors across biological, psychological, relational, developmental, cultural, and institutional domains.

### Step 3: Identify mechanisms and targets

Translate formulation into mechanisms: avoidance, arousal, belief, skill deficit, reinforcement, family sequence, shame, isolation, unmet need.

### Step 4: Sequence

Safety and stabilisation precede exposure. Alliance and consent precede challenge. Parent capacity may precede adolescent skills. Practical barriers may precede insight.

### Step 5: Match intervention to mechanism

Select the least complex intervention likely to affect the mechanism, within competence and evidence.

### Step 6: Explain the plan

Use plain language: “First we will help sleep and mornings become steadier. Then we will test the fear step by step. Your parents will work on responses that accidentally keep the avoidance going.”

### Step 7: Measure and revise

If outcomes do not improve, revisit formulation rather than adding random techniques.

## 5. Integration across This Book

A trauma-informed stabilisation plan may draw on somatic grounding, attachment-based co-regulation, CBT sleep skills, school consultation, and family psychoeducation. An eating or self-harm presentation may require medical care, family work, emotion regulation, and risk planning. Integration is therefore also interprofessional.

Narrative externalisation can reduce shame before exposure. Motivational interviewing can prepare a young person for skills work. Social cognitive theory can explain why mastery experiences are designed. Mentalization can guide family communication during behavioural changes. The theories become complementary when each is assigned a clear job.

## 7. Case Formulation as the Integrative Home

Integration needs a home more stable than fashion. Case formulation provides it. A good formulation is collaborative, developmental, cultural, testable, and linked to intervention.

Consider a sixteen-year-old with low mood, school absence, cannabis use, and conflict at home. A purely cognitive plan may miss sleep, peer belonging, parental exhaustion, and the function of cannabis. A purely systemic plan may miss depressive cognition and suicide risk. An integrative formulation can hold all of these while sequencing work:

1. risk and medical assessment;
2. sleep and morning routine;
3. motivational interviewing about cannabis and attendance;
4. behavioural activation and graded school return;
5. parent sessions on escalation and accommodation;
6. cognitive work on perfectionism and shame;
7. school adjustments and careers support.

The plan is integrated because each element has a reason and an order, not because many brand names appear.

## 8. Switching, Blending, and Sequencing

**Switching** means changing approach when phase or problem changes—for example, from stabilisation to trauma-focused work.

**Blending** means using compatible elements together—for example, narrative language within behavioural activation.

**Sequencing** means ordering interventions by dependency: safety before disclosure, parent session before joint communication, sleep before demanding exposure.

Confusion arises when practitioner switches because they are anxious, bored, or avoiding a rupture. Supervision should ask: What formulation changed? What mechanism is now targeted? What did the client consent to? What outcome will test the change?

## 9. Competence and Scope

Practitioners should distinguish between using an idea, using a technique, and delivering a treatment model. Reading about EMDR does not make one an EMDR practitioner. Borrowing scaling questions does not make a session solution-focused therapy. A grounding exercise does not constitute trauma treatment.

Training, supervised practice, fidelity, and referral pathways matter. Ethical integration includes saying: “I can help with stabilisation and family communication; for trauma processing I will refer or work jointly with a trained clinician.”

Documentation should reflect actual practice. Do not record model names for prestige. Record formulation, intervention, rationale, consent, response, and review.

## 10. Evidence and Evaluation

Comparative outcome research often finds modest differences among bona fide therapies, though specific treatments have advantages for specific disorders and outcomes. Integration should therefore be guided by disorder-specific evidence, mechanisms, client preference, developmental fit, and monitoring—not by the assumption that more techniques equal more benefit.

Routine outcome monitoring is especially important in integrative work because drift is easy. If measures and goals do not improve, options include strengthening alliance, revising formulation, increasing fidelity, changing sequence, involving systems, consulting, or referring. Adding another technique is only one possibility.

## 11. Cultural and Ethical Considerations

Integration can become cultural appropriation when practices are detached from context and used as exotic techniques. The practitioner should understand origin, purpose, evidence, and client preference, and should avoid importing religious or spiritual practices into a secular counselling frame unless the client independently identifies them as personal resources and professional boundaries permit appropriate acknowledgement without counsellor-led religious activity.

Client consent should cover major shifts in method. A young person who agreed to practical coaching may experience unexpected trauma exploration as betrayal. Parents should understand family involvement, and schools should receive only agreed information.

## 12. Key Terms

**Key Terms at a Glance**

- **Assimilative integration** — Importing ideas or techniques into a coherent home theory.
- **Common factors** — Relationship, expectancy, goal, feedback, and context elements shared across therapies.
- **Technical eclecticism** — Selecting techniques by fit and evidence without unifying theories.
- **Theoretical integration** — Combining concepts from multiple theories into a coherent framework.
- **Mechanism of change** — The process by which an intervention produces improvement.
- **Treatment drift** — Gradual departure from effective practice without formulation-based reason.

## 13. Chapter Summary

The integrative stance is disciplined pluralism. It respects the partial truth of theories, assigns each intervention a mechanism and a place in sequence, tells the client what is happening and why, and uses outcomes to correct course. Integration is not doing everything; it is knowing why one is doing this, now, with this young person.

## 14. Review and Discussion Questions

**Review and Discussion Questions**

1. Distinguish four forms of integration.
2. What questions prevent technical eclecticism from becoming incoherent?
3. Build a sequenced integrative plan for school refusal.
4. When is switching approach clinically justified rather than drift?
5. Why does integration require greater competence, not broader superficiality?
6. How should a major change in method be consented?
7. What outcome evidence should trigger reformulation?

## 15. Practice Activities

**Practice and Application**

### Activity 51.1 — Mechanism match

List five interventions from earlier chapters and identify the mechanism each targets.

### Activity 51.2 — Sequence defence

Write a ten-session plan for adolescent depression with self-harm risk. Defend the order of interventions.

### Activity 51.3 — Integration audit

Review a fictional session transcript and mark where theory changes are coherent, confusing, or ethically under-consented.

## 16. Annotated Reading Pathways

**For integration theory.** Norcross and Goldfried provide the major map of integration movements.

**For practice.** Multimodal and transtheoretical approaches show how assessment domains and readiness shape intervention choice.

**For evidence.** Read principles-of-change literature alongside disorder-specific guidelines so that common factors do not erase real differences among treatments.

# Practice Laboratory and Extended Worked Example

This laboratory turns **Theoretical Integration and the Integrative Stance** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is technical eclecticism, assimilative integration, and the discipline of a coherent theory of change. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The mechanism to keep in view is how assessment becomes a sequenced, reviewable plan whose parts are matched to mechanisms, people, settings, and evidence. The characteristic professional risk is collecting techniques without coherence, exceeding competence, or allowing documentation and institutional targets to replace the young person's goals. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

## A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in case conferences, supervision, school and clinic teams, teaching sessions, and service review, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and**

**eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Priya is fifteen and is seen in a school counselling service for low mood and withdrawal from friends. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Priya's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Priya explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The first intervention is deliberately modest. Priya chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Priya has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Priya can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Theoretical Integration and the Integrative Stance

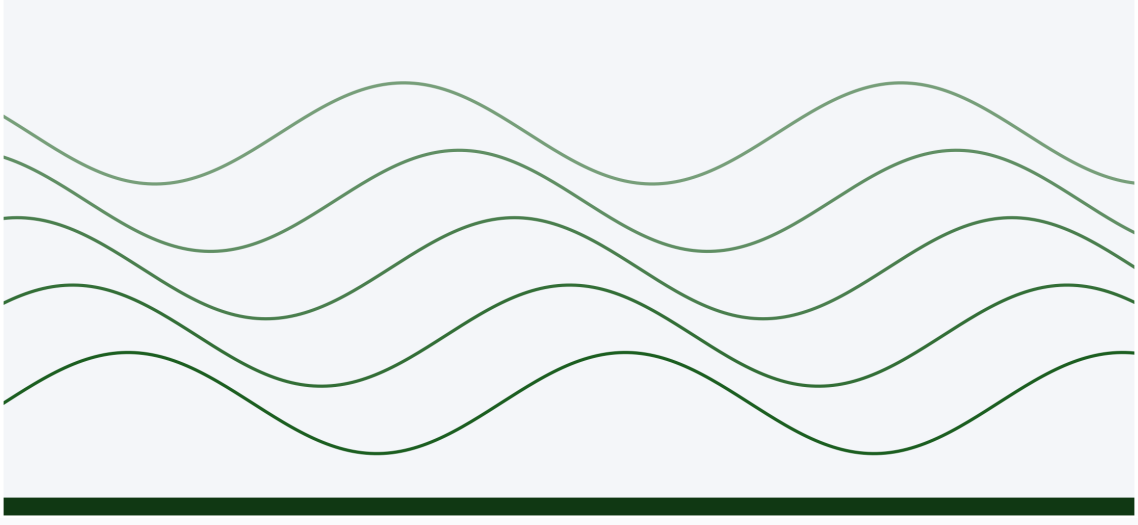
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Theoretical Integration and the Integrative Stance** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Theoretical Integration and the Integrative Stance** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Theoretical Integration and the Integrative Stance**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Theoretical Integration and the Integrative Stance to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 52

# Case Conceptualization and Treatment Planning

The five-part formulation, the mechanism of change, and the written treatment plan.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Distinguish description, diagnosis, formulation, and treatment plan.
- Construct a developmental, cultural, relational, and evidence-informed case conceptualization.
- Use predisposing, precipitating, perpetuating, protective, and presenting factors.
- Translate formulation into goals, interventions, sequencing, responsibilities, and review criteria.
- Write SMART but humane goals with adolescents and families.
- Identify risk, safeguarding, medical, educational, and social needs within a plan.
- Revise formulation in response to outcome data and new information.

## Chapter Overview

A diagnosis can name a pattern; it cannot by itself explain why this young person, in this family, in this school, at this time, is struggling in this way. Case conceptualization—also called formulation—is the bridge between assessment and treatment. It organises information into a testable explanation and identifies where change is possible.

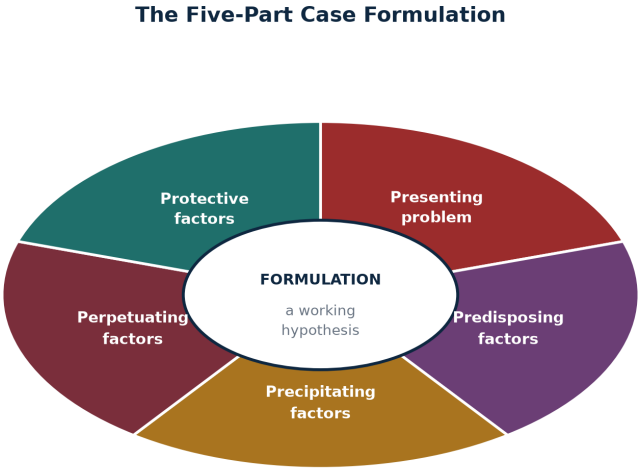


**Figure 52.44** The five-part formulation: presenting issues, predisposing factors, precipitating events, perpetuating mechanisms, and protective factors.

A good formulation is neither a biography nor a list of deficits. It is a concise, collaborative hypothesis that can be shared in developmentally appropriate language: what happened, what it meant, what keeps the problem going, what strengths exist, and what we will try first.

## 1. Description, Diagnosis, and Formulation

**Description** records what is happening: symptoms, behaviour, context, frequency, duration, severity, and impact.

**Diagnosis** classifies patterns according to recognised criteria. It can guide evidence, communication, eligibility, and prognosis, but may also stigmatise or obscure context.

**Formulation** explains development and maintenance for an individual in context. It includes strengths and systems as well as symptoms.

**Treatment plan** specifies goals, interventions, people, timeframe, measures, and review.

Confusing these levels leads to poor practice. “She avoids school because she has anxiety” is circular if anxiety is inferred only from avoidance. A formulation might instead identify panic sensations, catastrophic appraisal, avoidance relief, parental accommodation, bullying, sleep disturbance, and academic gaps—each suggesting intervention.

## 2. Sources of Information

Formulation draws on interviews with the young person, parents or carers, school information, previous records, observations, standardised measures, medical information, and the young person's creative or written expression. Disagreement between informants is not noise to erase; it reveals setting-specific patterns and different perspectives.

The counsellor should distinguish observation, report, inference, and speculation in records. “Mother reports that he refuses” is a report. “He appeared tense when discussing mathematics” is observation. “He may fear humiliation” is inference. “He is manipulative” is an unhelpful character judgement unless operationalised and evidenced.

## 3. The Five-Part Framework

### Presenting factors

Current concerns, symptoms, risks, functional impact, and the reason help is sought now.

### Predisposing factors

Temperament, neurodevelopment, early relationships, prior adversity, learning history, health, family patterns, cultural context, and earlier coping.

### Precipitating factors

Recent losses, transitions, conflicts, illness, bullying, academic pressure, family changes, or developmental demands that exceeded resources.

### Perpetuating factors

Avoidance, reinforcement, accommodation, insomnia, substance use, rumination, conflict cycles, inaccessible teaching, untreated pain, discrimination, and service fragmentation.

### Protective factors

Relationships, skills, interests, cultural and community resources, school belonging, prior successes, family commitment, practical resources, and hope.

The model becomes powerful when arrows are drawn between parts. A precipitant matters because of predisposition; a perpetuating loop explains why distress persists after the precipitant ends.

## 4. Levels of Formulation

A comprehensive adolescent formulation considers:

- biological and physical health;
- cognition, emotion, behaviour, and identity;
- attachment and family interaction;
- peers, school, and digital contexts;
- culture, language, discrimination, and community;
- material conditions and service systems;
- development and time.

Not every level requires intervention. The art lies in choosing leverage points: factors that are influential, changeable, acceptable to the client, and within available competence.

## 5. Collaborative Formulation

Young people should recognise themselves in the formulation without feeling reduced by it. Use their words where possible. Draw diagrams together. Offer uncertainty: “This is our best current map, not a final truth. What fits? What is missing? What feels wrong?”

Parents may need a parallel version focused on interactions and support, without disclosing confidential adolescent material. Schools need a functional, privacy-respecting summary focused on responses and adjustments.

A formulation that cannot be communicated is unfinished.

## 7. From Formulation to Goals

Goals should be meaningful, observable enough to review, achievable in sequence, and owned by the young person and family where appropriate. SMART criteria are useful if not applied mechanically. “Reduce

anxiety" is vague. "Attend first two lessons on four of five days for two weeks, using agreed entry route and break card" is reviewable. But human goals may also include feeling safer with mother, having one friend to eat with, or being able to sleep without checking locks. These can be scaled and described.

Distinguish:

- **Safety goals:** non-negotiable protection and risk reduction.
- **Stabilisation goals:** sleep, routine, regulation, attendance, basic functioning.
- **Change goals:** skills, relationships, beliefs, family patterns, academic participation.
- **Developmental goals:** autonomy, friendships, identity exploration, qualifications, transitions.
- **System goals:** school adjustments, coordinated care, parent support, practical resources.

A plan overloaded with goals becomes another experience of failure. Three to five active priorities are usually enough.

## 8. Treatment Planning

A complete plan states:

1. formulation summary;
2. goals and rationale;
3. interventions and who delivers them;
4. client, family, school, and professional responsibilities;
5. frequency, setting, and expected duration;
6. consent, assent, confidentiality, and information sharing;
7. risk and crisis arrangements;
8. measures and review dates;
9. criteria for intensifying, changing, referring, or ending;
10. practical barriers and solutions.

Sequencing is a clinical decision. Safety and engagement come before demanding processing. Parent work may precede joint sessions. Sleep and medical assessment may precede exposure. Skills may precede trauma narration. School changes may need to occur while individual therapy is still early.

## 9. Worked Example

**Presentation.** Amara, fifteen, has panic symptoms, school absence, falling grades, and nightly arguments.

**Formulation.** Predisposing: high sensitivity, perfectionism, previous bullying. Precipitating: school transition and public panic attack in assembly. Perpetuating: avoidance, reassurance seeking, mother leaving work to collect her, sleep reversal, academic backlog, teachers questioning absence in front of peers. Protective: strong writing ability, one trusted friend, committed grandmother, mother willing to change responses, school counsellor available.

**Plan.** Medical review; shared formulation; sleep routine; parent session on reassurance and collection thresholds; graded school return beginning with counsellor office and two lessons; interoceptive and situational exposure with trained practitioner; private teacher check-ins; academic triage so backlog does not become a second threat; weekly attendance and panic ratings; review after four weeks.

Notice that the plan is neither "CBT" as a slogan nor a collection of unrelated supports. Each item maps to a perpetuating factor.

## 10. Risk and Safeguarding in Plans

Risk formulation should identify static and dynamic factors, triggers, warning signs, protective factors, likely scenarios, and actions. Risk is not a score alone. Plans must name who does what, when, and how the young person can seek help.

Safeguarding concerns require action under local law and policy. Treatment planning cannot delay protection. Where parents are part of risk, information sharing and session structure change accordingly.

Plans should also consider risk created by treatment itself: exposure distress, family conflict after sessions, confidentiality breaches, transport home while dysregulated, online contact boundaries, and deterioration between appointments.

## 11. Review and Reformulation

Review asks:

- What improved, worsened, or stayed the same?
- Which formulation predictions were supported or disconfirmed?
- Was the intervention delivered as planned?
- Did the environment change?
- What does the young person say helped or harmed?
- Should intensity, focus, participants, or provider change?

Lack of progress is not automatically resistance. It may indicate wrong target, insufficient dose, poor alliance, unaddressed practical barriers, medical issues, family overload, or a formulation that flatters the professional's preferred theory.

Endings should be considered from the beginning. A plan that creates indefinite dependency without developmental purpose fails even if sessions feel warm.

## 12. Documentation Quality

Records should be accurate, respectful, and written as if the young person may read them—because in many systems they can. Avoid labels without evidence, speculative motives stated as fact, and copying forward outdated risk information. Date formulations, note whose views they represent, and record disagreements.

Treatment plans shared across agencies should include the minimum necessary information. Consent and legal basis for sharing must be clear.

## 13. Cultural and Ethical Considerations

Formulation can reproduce bias when culture is treated as pathology, poverty as parenting failure, or institutional harm as individual disorder. Include discrimination and material context explicitly, and ask the young person and family how they explain the problem.

Power matters in goal setting. A school may want compliance, a parent obedience, a service discharge, and the young person safety or freedom. The plan should identify whose goal each target serves and negotiate conflicts transparently.

Consent is ongoing. As formulation changes, the rationale for intervention should be re-explained. Young people should know what records exist, who can see summaries, and how to correct factual errors.

## 14. Key Terms

**Key Terms at a Glance**

- **Formulation** — A collaborative, testable explanation of how difficulties developed and are maintained.
- **Diagnosis** — Classification of a pattern according to recognised criteria.
- **Perpetuating factors** — Processes that maintain current difficulties.
- **Protective factors** — Relationships, capacities, and resources that buffer adversity.
- **Leverage point** — A changeable factor likely to influence the wider system.
- **Risk formulation** — Contextual explanation of risk scenarios, triggers, safeguards, and responses.

## 15. Chapter Summary

Case conceptualization turns information into judgement and judgement into a plan. Its quality is measured not by theoretical elegance but by whether it helps a real young person, family, and service decide what to do next, in what order, with what consent, and how they will know whether it worked.

## 16. Review and Discussion Questions

**Review and Discussion Questions**

1. Distinguish description, diagnosis, formulation, and plan.
2. Why is “avoidance because of anxiety” potentially circular?
3. Construct a five-part formulation for examination panic.
4. Convert three vague goals into reviewable goals without making them mechanistic.
5. What should happen when outcome data disconfirm a formulation?
6. How can school and parent goals conflict with the adolescent's goals?
7. Write a record entry that separates observation, report, and inference.

## 17. Practice Activities

**Practice and Application**

### Activity 52.1 — Five-part map

Create a five-part formulation for a fictional adolescent with low mood and family conflict. Draw arrows between factors.

### Activity 52.2 — Plan translation

Turn each perpetuating factor into one intervention, one responsible person, and one review measure.

### Activity 52.3 — Young-person version

Rewrite a professional formulation in 120 words of respectful language suitable for a fourteen-year-old.

## 18. Annotated Reading Pathways

**For formulation.** Johnstone and Dallos offer cross-theoretical depth; Kuyken and colleagues emphasise collaboration.

**For treatment planning.** Pair formulation texts with local safeguarding, consent, record-keeping, and service documentation standards.

**For practice.** Judge every formulation by whether it changes a decision. If it does not, it may be biography rather than formulation.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Case Conceptualization and Treatment Planning** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is the five-part formulation, the mechanism of change, and the written treatment plan. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is integration, formulation,

planning, measurement, coordination, ethics, and professional judgement. The mechanism to keep in view is how assessment becomes a sequenced, reviewable plan whose parts are matched to mechanisms, people, settings, and evidence. The characteristic professional risk is collecting techniques without coherence, exceeding competence, or allowing documentation and institutional targets to replace the young person's goals. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

## A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in case conferences, supervision, school and clinic teams, teaching sessions, and service review, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach,

peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Tunde is fifteen and is seen in a community adolescent clinic for grief following a major family change. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Tunde's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Tunde explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The first intervention is deliberately modest. Tunde chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Tunde has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Tunde can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the

young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language;

the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Case Conceptualization and Treatment Planning

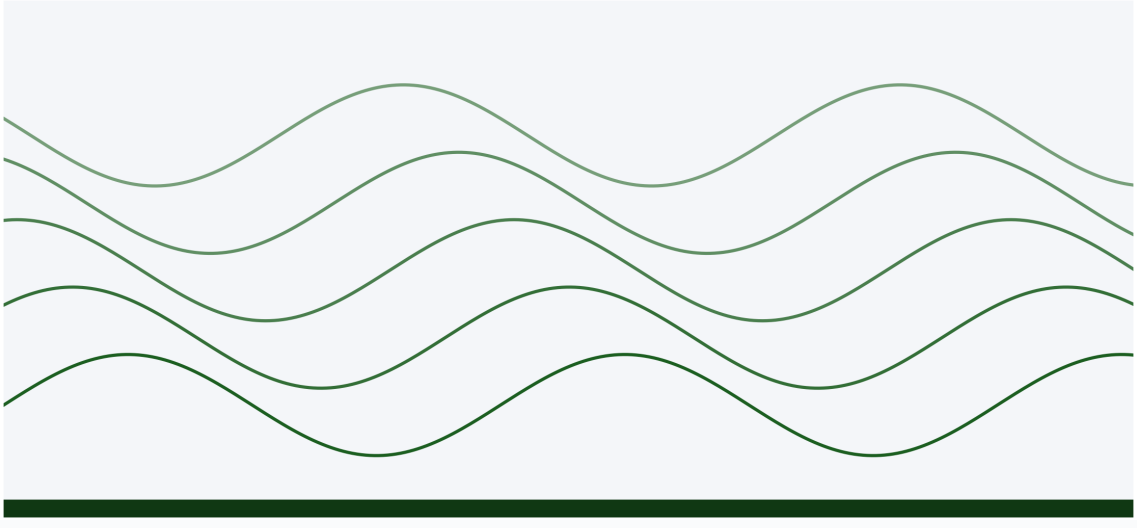
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Case Conceptualization and Treatment Planning** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Case Conceptualization and Treatment Planning** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Case Conceptualization and Treatment Planning**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Case Conceptualization and Treatment Planning to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 53

# Assessment and Outcome Monitoring in Counseling

Instruments, session notes, measurement-based care, and the ethical use of assessment data.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain purposes and limits of assessment in adolescent counselling.
- Select interviews, observations, rating scales, diaries, and functional measures appropriate to a referral question.
- Interpret scores using reliability, validity, norms, measurement error, and cultural fairness.
- Use routine outcome monitoring and session feedback to improve care.
- Distinguish symptom, functioning, wellbeing, personal recovery, and client-defined outcomes.
- Communicate assessment findings without reducing a young person to a score.
- Apply ethical standards for consent, privacy, data storage, testing, and feedback.

## Chapter Overview

Assessment is not the collection of everything knowable. It is the disciplined attempt to answer specific questions well enough to make decisions. What is happening? How severe and persistent is it? In which settings? What maintains it? What strengths and risks exist? What intervention is indicated? Is change occurring? Could assessment itself cause harm?

Outcome monitoring extends assessment across treatment. Brief, repeated measures can reveal improvement, stasis, deterioration, alliance problems, and mismatch between professional impressions and client experience. Used collaboratively, measures become conversation tools. Used mechanically, they become surveillance.

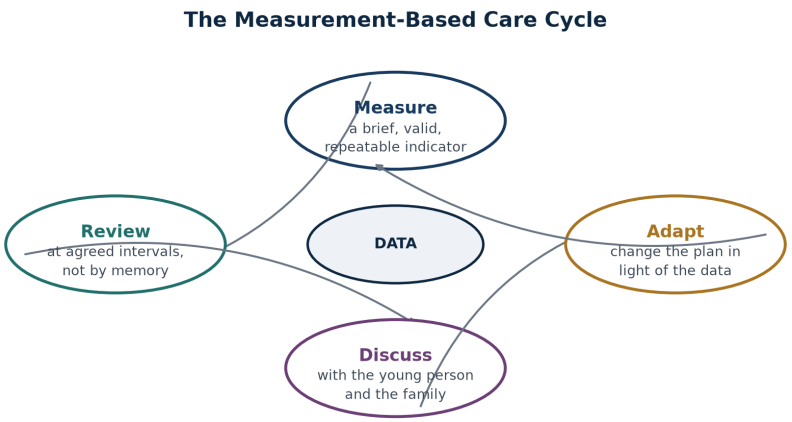


**Figure 53.45** Measurement-based care: assess, share feedback, adjust intervention, and reassess in a continuous loop.

## 1. Purposes of Assessment

Assessment may serve screening, diagnosis, formulation, risk identification, treatment selection, progress monitoring, service evaluation, safeguarding, education planning, or research. Each purpose requires

different evidence.

A screening tool identifies who needs fuller assessment; it does not diagnose. A symptom scale measures severity in a domain; it does not explain cause. An intelligence or attainment test answers specific educational questions; it does not summarise worth or potential. A risk scale may support structured judgement; it cannot predict an individual's future with certainty.

Students should always be able to complete the sentence: “This assessment is being used to decide…” If no decision follows, reconsider whether it is necessary.

## 2. Multi-Method, Multi-Informant Assessment

Adolescents behave differently across contexts. Self-report captures internal experience. Parent report captures home functioning and developmental history. Teacher report captures classroom participation and peer context. Observation captures interaction. Records capture attendance, attainment, incidents, and prior interventions.

Discrepancies are informative. A parent may report severe anxiety that teachers do not see because the student masks at school and collapses at home. A teacher may report inattention not reported by parents because classroom demands differ. Low agreement does not mean one informant is lying.

Interviews should be developmentally adapted: concrete examples, timelines, scaling, drawings, card sorts, digital timelines where appropriate, and permission to pause. Avoid leading questions in safeguarding and forensic contexts and follow local protocols.

## 3. Psychometric Foundations

**Reliability** concerns consistency: internal consistency, test–retest stability, and inter-rater agreement.

**Validity** concerns whether evidence supports a particular interpretation and use. A scale valid for screening adolescents in one population is not automatically valid for diagnosis in another language, culture, age group, or disability population.

**Norms** describe comparison samples. They must be relevant. A percentile is not a percentage correct and not a measure of personal value.

**Measurement error** means small score changes may not be meaningful. Reliable change indices and confidence intervals help, but clinical judgement and functional evidence remain essential.

**Sensitivity and specificity** matter in screening. A highly sensitive tool may identify many false positives; a specific tool may miss cases. Base rates affect predictive value.

**Cultural and linguistic fairness** requires more than translation. Concepts, idioms, response styles, family structures, and experiences of discrimination can alter meaning. Use validated adaptations and qualified interpreters; do not use children as interpreters for sensitive parental material.

## 4. Domains of Assessment

A comprehensive adolescent assessment may include:

- presenting concerns and client goals;

- mood, anxiety, trauma, psychosis, eating, substance use, sleep, and physical health;
- neurodevelopment, cognition, language, learning, and sensory needs;
- identity, culture, discrimination, and belonging;
- family relationships, caregiving capacity, and home safety;
- peer relationships, bullying, digital life, and exploitation risk;
- school functioning, attendance, attainment, and support;
- strengths, interests, coping, and previous helpful responses;
- risk to self, risk to others, vulnerability, and protective factors.

Comprehensive does not mean every domain in every case. It means the counsellor knows what has been omitted and why.

## 5. Functional and Idiographic Measures

Standardised scales compare a young person with groups. Idiographic measures track what matters to this person: number of panic episodes, nights slept in own bed, arguments lasting more than ten minutes, lessons attended, messages sent before checking, meals eaten with family, or a 0–10 rating of "feeling able to cope at school".

Goal-based outcomes invite the young person to define goals and rate progress. Session rating scales sample alliance and fit. Symptom diaries reveal timing and triggers.

Combining nomothetic and idiographic measures prevents two errors: treating population scores as the whole person, and treating personal impressions as immune to bias.

## 6. Further Reading for This Chapter

- Weisz, J. R., & Gray, H. A. (2008). Evidence-based psychotherapy in youth mental health. *Journal of Child Psychology and Psychiatry*.

## 7. Routine Outcome Monitoring

Routine outcome monitoring usually involves brief measures at intake, periodically during treatment, and at ending. Feedback is discussed with the young person and, where appropriate, family. Graphs can make change visible, including temporary worsening during exposure or family restructuring.

Evidence in youth services suggests monitoring can improve engagement and outcomes, especially when practitioners actually review feedback and adjust care. Collecting data without discussion wastes time and

may damage trust.

Choose measures that are:

- relevant to goals and population;
- brief enough to complete honestly;
- validated for age, language, and context where possible;
- sensitive to meaningful change;
- accessible in format and reading level;
- interpreted alongside functioning and client narrative.

Do not continue an ineffective treatment indefinitely because the relationship is pleasant. Do not terminate solely because a score crosses a threshold while functional evidence and risk point elsewhere.

## 8. Feedback Conversations

Feedback should be collaborative, plain-language, and developmentally appropriate. Start with the young person's view. Share what the measure can and cannot say. Invite disagreement.

A useful structure is:

1. “What has felt better, worse, or unchanged?”
2. “This scale suggests sleep and worry improved, but school functioning did not. Does that fit?”
3. “What might explain the difference?”
4. “What should we keep, change, or ask school or family to do?”
5. “When shall we check again?”

Parents may receive summary feedback consistent with consent and confidentiality. Schools should receive functional recommendations rather than raw clinical scores unless there is a clear, agreed purpose.

## 9. Risk Assessment

Risk assessment combines history, current presentation, context, and protective factors. Structured professional judgement is preferable to either unstructured intuition or blind score use.

Record risk formulation, not merely “low/medium/high”. Identify scenarios: What might happen? Under what triggers? How soon? How severe? What has prevented harm so far? What will each person do?

Risk changes. Reassess after disclosures, losses, conflict, substance use, service transitions, anniversaries, online events, and treatment ruptures. Safety plans should be accessible to the young person, written in their language, and reviewed rather than filed as proof that risk was “managed”.

## 10. Assessment in Schools and Services

School counsellors may contribute to special educational needs assessment, behaviour support, attendance planning, safeguarding, and wellbeing monitoring. Their role must remain distinct from discipline. Students should know whether information may enter school systems.

Service-level dashboards should monitor access, waiting times, completion, outcomes, deterioration, and equity by relevant demographic and access variables. A service can show average improvement while underserving disabled students, minority groups, or those with unstable housing. Aggregate success can conceal unequal benefit.

Assessment burden matters. Repeated long questionnaires can exhaust families and bias data toward those with time, literacy, digital access, and trust in institutions. Short forms, assistance, translated materials, and alternatives are equity measures.

## 11. Case Illustration: When the Score Improved but Life Did Not

**Presentation.** Jonah, sixteen, completes a depression scale every four weeks. His score improves from severe to moderate. The service proposes discharge.

**Review.** Jonah reports sleeping slightly better after medication review, but he has stopped attending college, no longer sees friends, and spends most days gaming in a dark room. His mother says arguments are fewer because “we've stopped asking anything of him.” The symptom score improved, but participation and developmental functioning worsened.

**Reformulation.** The original plan treated depressive symptoms without sufficiently targeting avoidance, academic backlog, peer withdrawal, and family accommodation. The revised plan adds behavioural activation, graded college return, a peer activity, family sessions on expectations, and goal-based measures for attendance and social contact.

The case illustrates why outcome is multidimensional. A score is evidence, not a verdict.

## 12. Ethics and Data Protection

Assessment requires informed consent or assent appropriate to age and capacity, explanation of purpose, voluntary participation where applicable, and clear limits. Some safeguarding or court-ordered assessments limit choice; honesty about compulsion is essential.

Test security, practitioner competence, storage, access, retention, and secondary use must follow professional and legal standards. Digital platforms introduce risks involving servers, metadata, shared devices, and automated scoring. Artificial intelligence tools should not be used to diagnose or make high-stakes decisions without validated evidence, human accountability, transparency, and local approval.

Reports should be respectful and readable. Avoid copying deficit language forward across years. Correct factual errors. Share findings in time to influence decisions.

## 13. Key Terms

**Key Terms at a Glance**

- **Reliability** — Consistency of measurement.
- **Validity** — Degree to which evidence supports an interpretation and use of a score.
- **Screening** — Brief identification of people who may need fuller assessment.
- **Idiographic measure** — A measure tailored to an individual's symptoms, goals, or behaviours.
- **Nomothetic measure** — A standardised measure permitting group comparison.
- **Reliable change** — Change larger than expected from measurement error.
- **Routine outcome monitoring** — Repeated measurement and feedback during care.
- **Structured professional judgement** — Risk assessment combining evidence-based factors with contextual formulation.

## 14. Chapter Summary

Good assessment answers decision-relevant questions using several methods and perspectives, acknowledges uncertainty, and respects the person beyond the score. Outcome monitoring makes counselling accountable to lived change: symptoms, functioning, relationships, participation, safety, and goals chosen by the young person.

## 15. Review and Discussion Questions

**Review and Discussion Questions**

1. Why does a screening score not establish diagnosis?
2. Explain reliability and validity with a school wellbeing scale example.
3. Why can parent, teacher, and adolescent reports legitimately disagree?
4. Design one standardised and one idiographic outcome measure for panic-related school avoidance.
5. What should happen when symptom scores improve but functioning worsens?
6. Identify three equity problems in digital outcome collection.
7. Write a feedback statement that shares uncertainty respectfully.

## 16. Practice Activities

**Practice and Application**

### Activity 53.1 — Measure selection

For adolescent social anxiety, select a screening tool, symptom measure, functional measure, and client-defined goal measure. Justify each.

### Activity 53.2 — Feedback role-play

Practise sharing a graph showing deterioration during exposure therapy without alarming or falsely reassuring a parent.

### Activity 53.3 — Report revision

Rewrite a deficit-heavy assessment paragraph into accurate, respectful, formulation-linked language.

## 17. Annotated Reading Pathways

**For psychometrics.** The testing standards are essential before using standardised instruments beyond screening.

**For youth outcomes.** Read child mental health outcome literature on reliable change, goal-based outcomes, and the limits of symptom-only endpoints.

**For implementation.** Monitoring works when feedback changes decisions. Study service examples where data review is built into supervision and team meetings.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Assessment and Outcome Monitoring in Counseling** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is instruments, session notes, measurement-based care, and the ethical use of assessment data. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The mechanism to keep in view is how assessment becomes a sequenced, reviewable plan whose parts are matched to mechanisms, people, settings, and evidence. The characteristic professional risk is collecting techniques without coherence, exceeding competence, or allowing documentation and institutional targets to replace the young person's goals. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in case conferences, supervision, school and clinic teams, teaching sessions, and service review, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable,

and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Sofia is fifteen and is seen in a family support service for sleep disruption, irritability, and falling participation. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Sofia's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Sofia explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through

repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The first intervention is deliberately modest. Sofia chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Sofia has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Sofia can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.

- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Assessment and Outcome Monitoring in Counseling

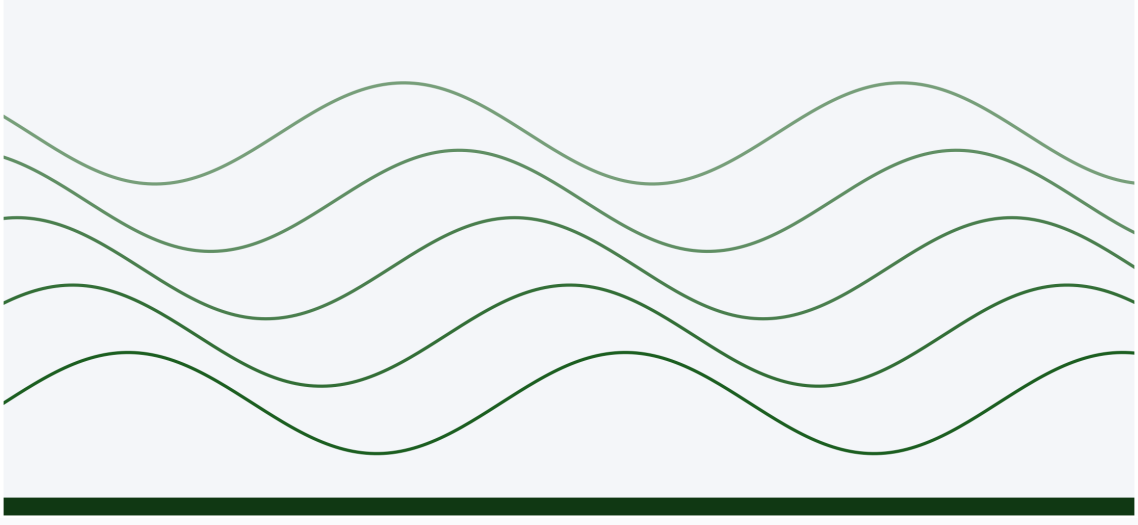
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Assessment and Outcome Monitoring in Counseling** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Assessment and Outcome Monitoring in Counseling** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Assessment and Outcome Monitoring in Counseling**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Assessment and Outcome Monitoring in Counseling to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 54

# Termination, Evaluation, and the Ethics of Endings

Planned termination, relapse prevention, transfer, and the evaluation of outcome.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Explain why endings are active therapeutic events rather than administrative afterthoughts.
- Distinguish planned termination, transfer, interruption, dropout, and service-imposed ending.
- Prepare adolescents and families for endings from the beginning of treatment.
- Evaluate progress, consolidate learning, and plan relapse prevention.
- Manage practitioner transitions and endings caused by placement, funding, school leaving, or risk escalation.
- Address abandonment, dependency, gratitude, anger, and unfinished business ethically.
- Write closing summaries and referrals that protect continuity and dignity.

## Chapter Overview

Every counselling relationship ends. It may end because goals are achieved, time expires, school terms turn, a practitioner leaves, a family moves, risk requires another service, or the young person stops attending. Endings can consolidate autonomy or repeat experiences of rejection and disappearance. Ethical practice therefore treats termination as part of treatment from the first session.

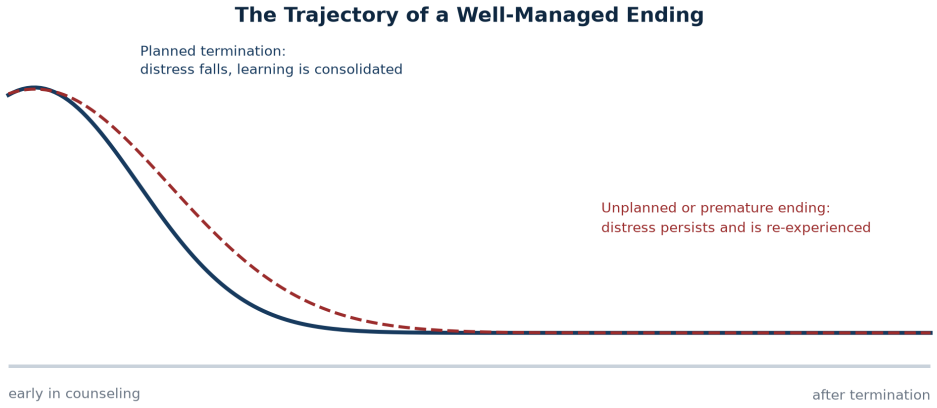


**Figure 54.46** The termination path: review beginnings, consolidate change, rehearse future challenges, plan support, and close with a clear door back to help.

## 1. Why Endings Matter Developmentally

Adolescents are already negotiating separations: changing schools, shifting friendships, leaving home, losing relatives, moving between care placements, and approaching adult services. Counselling endings can echo these transitions. A young person with abandonment sensitivity may test the ending by missing sessions, devaluing progress, becoming suddenly worse, or leaving first. These responses are not manipulation by default; they are information about attachment, control, and grief.

A planned ending offers a different experience: the date is known, feelings can be named, progress is reviewed, anger and sadness are permitted, and help-seeking in the future is framed as competence rather

than failure.

## 2. Types of Ending

**Planned mutual termination** follows goal review and relapse planning.

**Time-limited ending** is built into a brief model and should be explicit from the outset.

**Transfer** occurs when needs exceed competence or setting, practitioner leaves, or a specialist service is indicated.

**Interruption** may result from illness, placement move, family crisis, transport failure, or school exclusion. It calls for active follow-up within policy.

**Dropout or unilateral ending** may signal dissatisfaction, improvement, practical barriers, shame, family conflict, or avoidance. Services should attempt respectful contact without harassment.

**Service-imposed ending** due to funding, age limits, non-attendance policies, or risk thresholds requires transparency, appeal routes where available, and transition planning. Calling it “client disengagement” does not erase institutional responsibility.

## 3. Beginning with the End in Mind

At intake, explain likely duration, review points, and what may trigger referral or ending. For time-limited work, name the number of sessions when known. For open-ended work, schedule periodic reviews.

Questions include:

- How will we know this has helped enough?
- What would you like to be different by our review?
- What concerns you about ending or changing counsellor?
- Who else should be involved in planning next steps?

This is not pessimism. A visible horizon helps clients use time and reduces dependence on the counsellor as the sole container of progress.

## 4. Evaluating Whether to End

Evaluation draws on symptoms, functioning, goals, relationships, participation, safety, client experience, and developmental trajectory. A young person may still have symptoms yet possess skills, supports, and a plan that make counselling no longer the right intensity. Another may score below a clinical threshold but remain isolated and unsafe.

Consider:

1. Have agreed goals been met or sufficiently progressed?
2. Can gains be maintained with ordinary supports?
3. Are risks understood and managed by a wider plan?
4. Has the young person internalised skills and help-seeking routes?

5. Are family and school responses supporting change?
6. Would continued sessions add value or create dependency?
7. Is another service better matched to remaining needs?

Ending from counselling does not mean ending all support. Step-down may involve mentoring, school check-ins, family support, peer groups, primary care, or planned booster sessions.

## 5. The Termination Phase

The final phase usually includes reviewing the original concerns, identifying changes and how they occurred, naming unresolved issues, rehearsing future challenges, updating safety and relapse plans, and deciding what records or summaries will be shared.

Young people may benefit from concrete artefacts: a coping card, letter to future self, timeline of progress, list of trusted adults, or summary in their own words. Such artefacts require consent and should not disclose sensitive material if lost or shared.

Booster sessions can be ethical when planned with purpose and limits. Open-ended “come back any time” promises should not be made where service rules do not permit them.

## 7. Working with Reactions to Ending

Reactions may include relief, pride, indifference, grief, anger, anxiety, idealisation, devaluation, symptom return, or sudden requests for personal contact. Parents may feel gratitude, fear of losing support, or pressure to declare success. Practitioners may feel sadness, guilt, rescue urges, or relief; these require supervision.

Useful interventions include normalising mixed feelings, revisiting previous endings, allowing dissatisfaction to be spoken, and distinguishing ending counselling from ending care. Avoid interpreting every reaction as pathology. Sometimes anger is a proportionate response to an abrupt institutional decision.

Where deterioration occurs near ending, assess genuinely rather than assuming it is only separation protest. Extend or refer when risk warrants. At the same time, do not let every fluctuation indefinitely postpone a planned ending; build confidence in the wider support plan.

## 8. Practitioner Departure and Transfer

When a practitioner leaves, tell the young person as early as policy and certainty permit. Explain what will happen to records, who will receive a summary, whether a joint handover is possible, and what choices exist. Do not promise personal contact outside service systems.

A transfer summary should be concise and relevant: reason for referral, formulation, risk and safeguarding, interventions and response, current goals, medication or medical contacts where relevant, family and school arrangements, and what helps. Avoid sending entire process notes unless legally and clinically justified.

Joint handover sessions can help but may also overload. The young person should consent where possible and know what will be discussed.

## 9. Non-Attendance and Unplanned Endings

Services need humane non-attendance procedures. A missed appointment may indicate improvement, fear, transport problems, family conflict, forgetting, shame, or a confidentiality breach. Follow local policy, safeguarding duties, and the agreed contact method. Messages should not reveal sensitive information to whoever controls the phone.

Document attempts, close episodes transparently, and tell referrers what has occurred. Where risk is high, non-attendance may require escalation rather than administrative closure.

Practitioners should also examine service contributions to dropout: waiting times, inaccessible locations, culturally unsafe practice, poor alliance, inconvenient scheduling, or failure to involve the young person in goals.

## 10. Case Illustration: Ending Without Disappearing

**Presentation.** Tobi, seventeen, has completed twenty sessions for panic and school avoidance. Attendance and functioning have improved. The counsellor is leaving the school service in five weeks.

**Process.** The counsellor tells Tobi immediately rather than waiting until the final session. Tobi initially says, “Fine, I was going to stop anyway,” then misses the next appointment. A brief agreed text is sent without clinical detail. At the following session, Tobi acknowledges anger: adults “always go once things are working”.

The ending phase reviews the original panic diary, the mastery ladder, and the teacher arrangements that now belong to school rather than counselling. Tobi writes a future-self plan: early signs, first three steps, trusted adult, tutor check-in, and when to seek health care. A joint meeting with the school's pastoral lead confirms continuation of the entry and break plan. Tobi chooses not to transfer to another counsellor but knows the re-referral route.

At the final session, Tobi says the ending is “annoying but normal”. The phrase is clinically meaningful: separation has been survived without disappearance, punishment, or pretence that it does not matter.

## 11. Evaluation of Services and Practitioner Learning

Termination data should be examined by reason: planned completion, transfer, dropout, service capacity, moving, risk escalation, or dissatisfaction. Services should ask whether endings differ by ethnicity, disability, language, gender, care status, or deprivation. High completion rates may reflect selection rather than quality.

Client feedback at ending should include whether goals mattered, whether the young person felt respected, what was unhelpful, and what should change. Practitioner reflection can identify recurring difficulties with dependency, conflict, boredom, rescue, or avoidance of endings.

Evaluation is not only discharge measurement. It asks whether gains persist, whether referrals were accepted, whether school and family systems maintained changes, and whether re-referral reflects relapse, appropriate help seeking, or failure of step-down support.

## 12. Ethical Considerations

Ethical endings require honesty about time, competence, funding, and availability. Do not prolong treatment for practitioner income, training needs, research, or attachment. Do not terminate abruptly to punish non-compliance except where safety or professional boundaries require immediate action and policy supports it.

Post-termination contact should follow organisational and professional rules. Social media contact, personal messaging, gifts, and dual relationships require particular care with minors and former minor clients. Gratitude can be acknowledged warmly without creating private channels.

Closing records should distinguish outcome at ending from speculation about the future. Referrals should not exaggerate or minimise risk to secure acceptance. The young person should know what is being sent, subject to safeguarding exceptions.

## 13. Key Terms

**Key Terms at a Glance**

- **Termination** — The planned or unplanned conclusion of a counselling relationship.
- **Booster session** — A time-limited follow-up session to review maintenance and problem-solve setbacks.
- **Treatment dropout** — Client-initiated ending before agreed completion, whose meaning requires inquiry rather than assumption.
- **Step-down care** — Movement to a lower-intensity or more community-based form of support.
- **Handover** — Planned transfer of relevant information and responsibility between practitioners or services.
- **Relapse prevention** — Identification of warning signs, high-risk contexts, coping responses, and help-seeking routes.

## 14. Chapter Summary

Ethical endings are honest, prepared, evaluative, and connective. They return authorship to the young person, transfer useful knowledge to the systems that remain, and leave a clear route back to help. A good ending does not pretend the relationship did not matter; it demonstrates that mattering does not require permanence.

## 15. Review and Discussion Questions

**Review and Discussion Questions**

1. Why should termination be discussed at intake?
2. Distinguish planned termination, transfer, interruption, dropout, and service-imposed ending.
3. What outcomes besides symptom scores should inform ending?
4. How might deterioration near ending be understood without dismissing real risk?
5. Write a transfer summary structure that protects privacy.
6. What makes a booster session ethical or unethical?
7. How can services detect inequitable patterns in endings?

## 16. Practice Activities

**Practice and Application**

### Activity 54.1 — Ending letter

Draft a closing summary for a fictional adolescent in respectful language they could keep.

### Activity 54.2 — Departure conversation

Role-play telling a sixteen-year-old that you are leaving in four weeks, including likely anger and practical choices.

### Activity 54.3 — Ending audit

Create categories for auditing one year of case closures and identify what each category might reveal about service quality.

## 17. Annotated Reading Pathways

**For clinical process.** Termination research helps practitioners recognise common client and therapist reactions and avoid abrupt endings.

**For ethics.** Professional frameworks and local safeguarding policies should govern post-termination contact, record transfer, and non-attendance follow-up.

**For service evaluation.** Combine outcome scores with reason for ending, client experience, equity data, and follow-up where feasible.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Termination, Evaluation, and the Ethics of Endings** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is planned termination, relapse prevention, transfer, and the evaluation of outcome. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The mechanism to keep in view is how assessment becomes a sequenced, reviewable plan whose parts are matched to mechanisms, people, settings, and evidence. The characteristic professional risk is collecting techniques without coherence, exceeding competence, or allowing documentation and institutional targets to replace the young person's goals. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in case conferences, supervision, school and clinic teams, teaching sessions, and service review, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the

next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Daniel is fifteen and is seen in an integrated school and health team for conflict with parents about autonomy. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Daniel's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Daniel explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The first intervention is deliberately modest. Daniel chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Daniel has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Daniel can describe the

pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?

- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Termination, Evaluation, and the Ethics of Endings

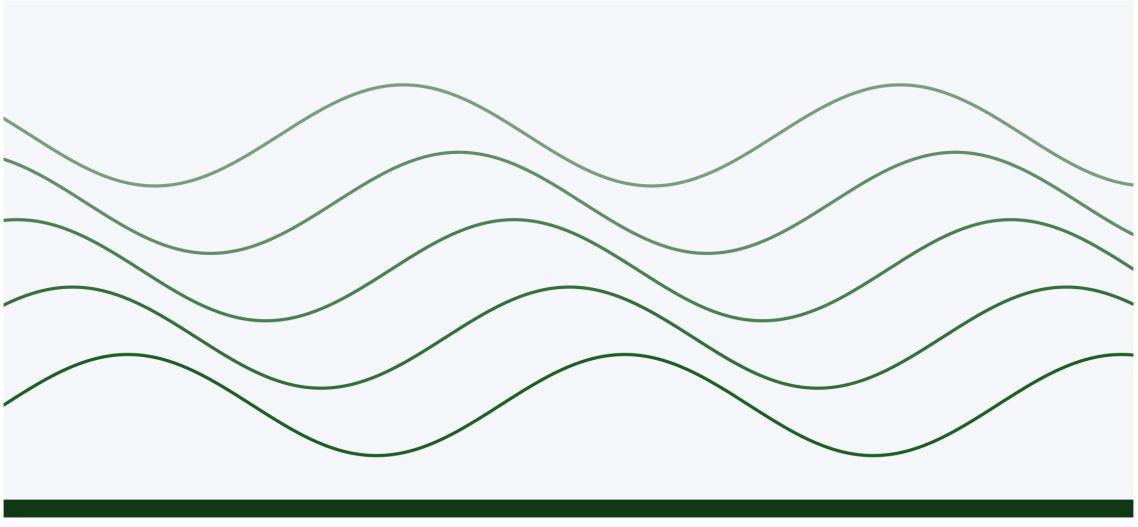
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Termination, Evaluation, and the Ethics of Endings** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Termination, Evaluation, and the Ethics of Endings** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Termination, Evaluation, and the Ethics of Endings**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Termination, Evaluation, and the Ethics of Endings to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 55

# Teletherapy and Technology in Counseling with Youth

Secure video practice, telehealth with minors, and digital ethics.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Compare video, telephone, text-based, asynchronous, app-supported, and blended counselling.
- Assess suitability and risk for remote work with children and adolescents.
- Establish privacy, identity, location, emergency, and safeguarding procedures.
- Adapt alliance building, play, family work, and outcome monitoring to digital settings.
- Evaluate apps, platforms, digital records, and artificial intelligence claims.
- Address digital equity, accessibility, online exploitation, and technology-related presenting problems.

## Chapter Overview

Technology is no longer an add-on to adolescent life or counselling. Young people form friendships, learn, play, seek help, experience bullying, explore identity, and manage distress through digital environments. Teletherapy can increase access for rural families, disabled young people, those with transport barriers, and students who find remote contact less intimidating. It can also create privacy risks, weaken observation, complicate safeguarding, and exclude those without devices, connectivity, or a safe room.

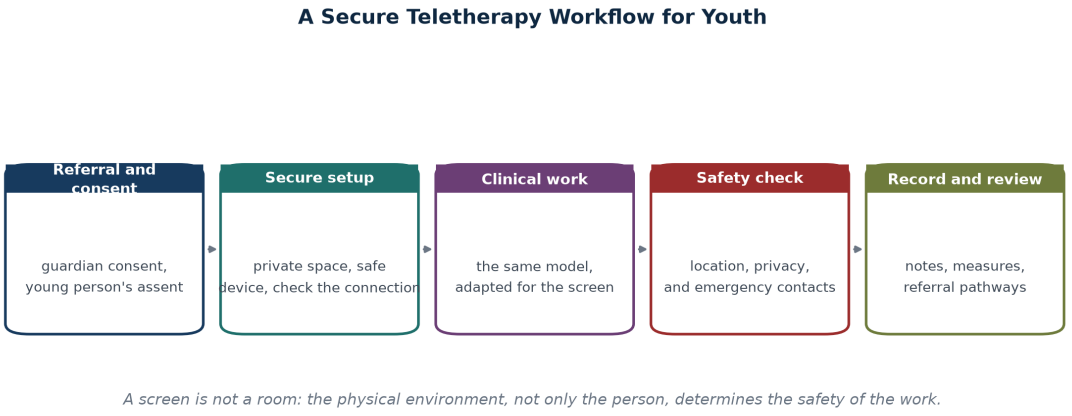


**Figure 55.47** A telehealth workflow: suitability assessment, consent, privacy and emergency checks, session adaptation, documentation, and review.

## 1. Modalities

**Synchronous video** most closely resembles in-person work and supports observation, family sessions, and visual materials.

**Telephone** may feel safer for some adolescents and avoids appearance concerns, but removes visual cues and can make silence harder to interpret.

**Live text or chat** can help young people who struggle to speak, but slows affect recognition and creates records requiring careful governance.

**Asynchronous messaging** permits reflection between contacts but risks boundary confusion, delayed crisis response, and expectations of continuous availability.

**Apps and digital tools** may support mood tracking, skills practice, exposure hierarchies, sleep routines, and outcome measures. They should supplement—not silently replace—clinical judgement.

**Blended care** combines remote and in-person sessions according to purpose: assessment or family work in person, brief reviews remotely, school consultation by secure video, and digital homework between sessions.

## 2. Evidence and Suitability

Research generally supports teletherapy effectiveness for several mental health conditions, including many anxiety and depression interventions, with outcomes often comparable to in-person treatment when appropriately delivered. Youth evidence is growing but varies by age, condition, platform, and degree of caregiver involvement.

Suitability is individual. Consider developmental level, attention, language, neurodivergence, sensory needs, risk, home privacy, technology access, family conflict, and the nature of interventions. Remote work may be unsuitable where there is acute risk without local support, severe dissociation, unsafe home monitoring, complex safeguarding investigation, or need for physical observation and intervention. Unsuitability is not permanent; reassess as circumstances change.

## 3. Before the First Remote Session

A technology-specific assessment and agreement should cover:

- identity verification and who else may be present;
- the young person's physical location at each session;
- privacy and interruptions;
- emergency contact and local crisis resources;
- a backup plan if connection fails;
- recording prohibition or consent;
- chat, email, and messaging boundaries;
- parent or carer involvement;
- school or service network security;
- what happens if abuse or risk is observed or disclosed.

The practitioner should also test camera, audio, accessibility features, captions, screen sharing, and data storage. Professional backgrounds and attire matter less than audibility, lighting, confidentiality, and freedom from household interruptions on the practitioner's side.

## 4. Privacy in Real Homes

A bedroom is not automatically private. Siblings may listen, parents may monitor, doors may lack locks, and devices may be shared. Ask what the young person can safely say and what should be avoided. Agree signals for “I can't speak freely”, options to switch to chat, or rescheduling without giving a reason that creates danger.

Headphones can increase privacy but reduce awareness of surroundings. The practitioner should periodically check who is nearby, especially before family conflict, sexuality, identity, abuse, or self-harm discussions.

School-based teletherapy requires a private room, not a corridor or shared office. Staff must know a session is occurring without receiving content.

## 5. Alliance and Presence Online

Digital presence requires explicit warmth. The practitioner names delays, looks toward camera periodically, summarises more often, checks understanding, and tolerates silence without filling it anxiously. Young people may prefer camera off at first; explore reasons rather than impose visibility unless assessment or safeguarding requires otherwise.

Creative adaptations include shared whiteboards, drawing applications, digital scaling, screen-shared worksheets with consent, music or images chosen by the young person, and movement breaks. The practitioner should not record, screenshot, or save shared material without agreement and a record-keeping rationale.

## 7. Risk, Safeguarding, and Emergencies

At each session, confirm location and a contact number. Know local emergency and safeguarding routes for the young person's actual location, not merely the clinic's address. If risk escalates, keep the young person connected if safe, involve agreed emergency contacts, and follow local procedures.

Remote observation may reveal concerning backgrounds, voices, injuries, or another person directing answers. The practitioner should not investigate beyond their role where forensic or safeguarding specialists are required, but should document observations accurately and act promptly.

Online exploitation, image sharing, coercion, trafficking, and digital abuse may form part of the presenting problem. Preserve evidence according to specialist advice and law; do not ask a young person to forward illegal images to the counsellor. Involve safeguarding leads and appropriate authorities.

## 8. Family and Group Work Online

Remote family sessions require stronger choreography. Agree who speaks, how interruptions are handled, whether chat is used, and how a pause occurs. Separate breakout conversations need technical and confidentiality planning.

Group teletherapy requires screening, agreements about recording and screenshots, management of private messaging among members, and attention to who may be off-camera. Confidentiality cannot be guaranteed by the practitioner; this limit must be explicit.

Parents may value remote access, but a parent's presence in an adjoining room can change an adolescent's disclosure. Structure parent check-ins at the beginning or end rather than invisible monitoring throughout.

## 9. Digital Tools, Apps, and AI

Evaluate digital tools by asking:

1. What clinical problem does it address?
2. What evidence supports it for this age group?
3. What data are collected, where stored, and who can access or sell them?
4. Does it encourage unsafe comparison, compulsive use, or crisis delay?
5. Is it accessible and culturally appropriate?
6. Can the young person delete data and stop use?
7. Does it clearly direct users to human help in crisis?

Artificial intelligence chatbots and automated assessment tools require particular caution. They may simulate empathy without understanding, produce inaccurate advice, reinforce bias, or create dependency. They should not independently diagnose, manage risk, or replace human care for minors. Any organisational use requires validation, transparency, safeguarding design, data governance, and accountable human oversight.

## 10. Technology-Related Presenting Problems

Digital life can be context, resource, symptom, and stressor at once. Assessment should avoid moral panic and ask functionally:

- What does the young person gain online—belonging, mastery, escape, identity, income, creativity?
- What is displaced—sleep, movement, study, family contact, offline friendship?
- What harms occur—bullying, comparison, coercion, gambling-like mechanics, pornography, misinformation, contact risks?
- What control exists—algorithms, notifications, peer expectations, fear of missing out?

- What change does the young person want?

Interventions may involve sleep routines, notification design, platform safety, family agreements, alternative belonging, school anti-bullying action, and treatment of underlying anxiety, depression, loneliness, or neurodevelopmental needs. Confiscation alone rarely teaches regulation and may remove support networks.

## 11. Case Illustration: Therapy from a Parked Car

**Presentation.** Sena, seventeen, is referred for anxiety. She joins video sessions from a parked car outside home because her younger siblings share her room and her mother listens at doors. The practitioner initially treats the car as a privacy solution.

**Assessment.** Sena is not licensed to drive alone to a safer place, the car is hot, sessions are rushed before a parent returns, and she cannot use grounding movement. On one occasion she becomes distressed while a parent is knocking on the window.

**Reformulation.** Remote access solved travel but not privacy or safety. The service arranges a hybrid plan: fortnightly in-person sessions at a youth centre, brief remote check-ins only for practical planning, and a written agreement that sensitive work occurs in person. Sena's mother receives general guidance on privacy without session content.

The case shows that technological convenience must be tested against embodiment, safety, confidentiality, and the young person's actual environment.

## 12. Equity and Accessibility

Digital exclusion can mirror social inequality. Services should ask about devices, data costs, connectivity, shared space, disability access, language, and digital literacy. Offer telephone or in-person alternatives, captioning, interpreters, low-bandwidth options, and assistance with setup.

Accessibility includes screen-reader compatibility, keyboard navigation, visual contrast, reduced motion, and alternatives for young people who find eye contact or camera self-view distressing. Accessibility is not an enhancement; it is equitable care.

## 13. Key Terms

**Key Terms at a Glance**

- **Teletherapy** — Counselling delivered through telecommunications technology.
- **Blended care** — Planned combination of in-person, remote, and digital-supported care.
- **Asynchronous contact** — Communication exchanged with time delays, such as secure messaging.
- **Digital equity** — Fair access to devices, connectivity, skills, privacy, and accessible design.
- **Online exploitation** — Coercive or abusive use of digital communication for sexual, financial, or other exploitation.
- **Data governance** — Rules and accountability for collecting, storing, accessing, sharing, and deleting data.

## 14. Chapter Summary

Technology can widen the counselling room or quietly shrink it. Ethical teletherapy begins before login: suitability, location, privacy, emergency arrangements, accessibility, and boundaries. During sessions, the practitioner adapts presence and methods. Afterward, records and data require the same care as the conversation itself.

## 15. Review and Discussion Questions

**Review and Discussion Questions**

1. Compare video, telephone, chat, asynchronous messaging, and blended care for adolescents.
2. List ten checks required before a first remote session.
3. How can a private home still be an unsafe therapy setting?
4. What should happen if a young person's location changes to another jurisdiction?
5. Evaluate a fictional mental health app using the seven questions in this chapter.
6. Why should AI chatbots not independently manage adolescent risk?
7. Identify three digital equity adjustments a service can make.

## 16. Practice Activities

**Practice and Application**

### Activity 55.1 — Remote-session agreement

Draft a one-page agreement covering privacy, location, recording, messaging, emergencies, and connection failure.

### Activity 55.2 — Modality match

For panic treatment, family conflict, grief, and social skills practice, choose a modality and defend the choice.

### Activity 55.3 — Privacy rehearsal

Role-play discovering that a parent is listening outside the door during a video session with a sixteen-year-old.

## 17. Annotated Reading Pathways

**For guidelines.** Use current national and organisational telemental health standards because technology and law change quickly.

**For evidence.** Read youth-specific systematic reviews and distinguish guided digital interventions from unguided apps.

**For ethics.** Combine data protection, safeguarding, digital rights, and professional boundary guidance before adopting any new platform.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Teletherapy and Technology in Counseling with Youth** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is secure video practice, telehealth with minors, and digital ethics. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The mechanism to keep in view is how assessment becomes a sequenced, reviewable plan whose parts are matched to mechanisms, people, settings, and evidence. The characteristic professional risk is collecting techniques without coherence, exceeding competence, or allowing documentation and institutional targets to replace the young person's goals. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | "I know what this is and what may be shared." | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | "Adults are not treating one setting as my whole life." | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | "The problem has a pattern; I am not simply the problem." | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | "This account fits, partly fits, or needs changing." | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | "These goals are mine as well as the service's." | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | "I have a way to begin, not just an instruction." | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in case conferences, supervision, school and clinic teams, teaching sessions, and service review, adapting dose and pace to development and state. | "The work is challenging but understandable and stoppable." | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | "This is not only something I do in a counselling room." | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | "A setback leads to inquiry, not blame." | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | "Adults are changing some conditions too." | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | "I can explain what helps and why." | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | "Ending is planned; I am not disappearing from care." | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable,

and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Nia is fifteen and is seen in a school counselling service for shame after academic failure. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Nia's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Nia explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated

questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The first intervention is deliberately modest. Nia chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Nia has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Nia can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.

- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Teletherapy and Technology in Counseling with Youth

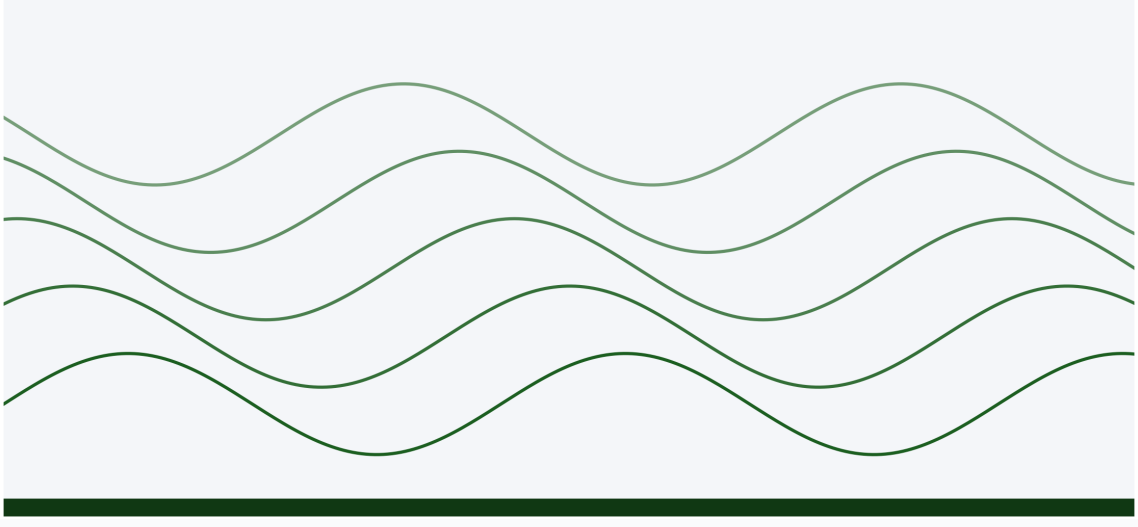
**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Teletherapy and Technology in Counseling with Youth** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Teletherapy and Technology in Counseling with Youth** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Teletherapy and Technology in Counseling with Youth**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Teletherapy and Technology in Counseling with Youth to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 56

# School Counseling Practice and Consultation

The school counselor's role, the consultation model, and the ethics of working in an institutional setting.

## Learning Objectives

By the end of this chapter, the student should be able to:

- Describe the school counsellor's roles in direct counselling, consultation, prevention, advocacy, coordination, and systems change.
- Distinguish counselling from discipline, attendance enforcement, and behaviour management.
- Build ethical confidentiality practices within a school.
- Consult with teachers and families using collaborative problem-solving.
- Develop tiered supports within a multi-tiered system.
- Respond to crises, safeguarding concerns, and school-wide trauma.
- Evaluate school counselling outcomes and equity.

## Chapter Overview

Schools are where adolescents spend much of their social lives, encounter evaluation and belonging, form peer relationships, and become visible to adults outside the family. School counselling therefore cannot be only a quiet room and a waiting list. It includes brief individual work, groups, classroom and whole-school prevention, consultation with teachers, family collaboration, crisis response, referral, advocacy, and examination of the systems that produce distress.

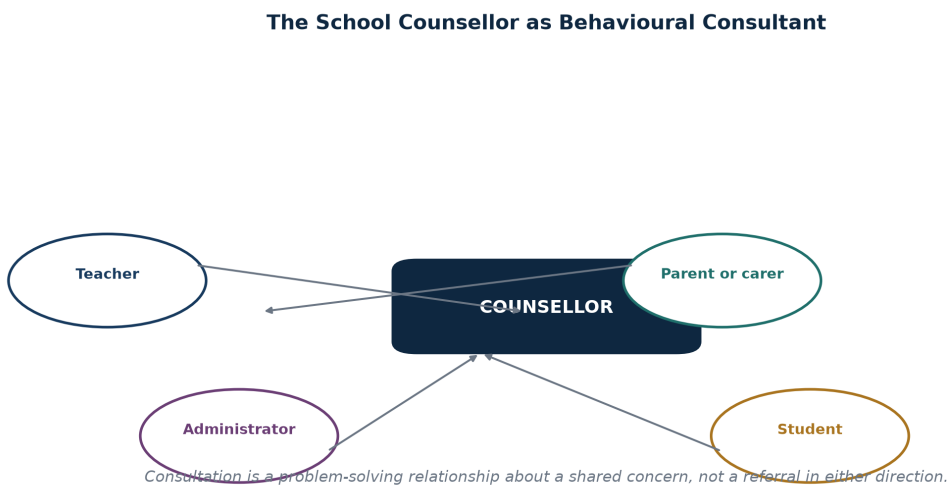


**Figure 56.48** School consultation: counsellor, teacher, family, and student perspectives converge around a shared problem definition and classroom plan.

## 1. The Distinctive School Context

School counsellors work inside the institution that may be both resource and stressor. A counsellor can help a student cope with examination pressure while also questioning public ranking practices. They can support behaviour plans while resisting the use of counselling as punishment. They can share functional information with teachers while protecting confidential disclosures.

This dual position requires role clarity. At the beginning of work, explain:

- what counselling is and is not;
- who can refer and why;
- what remains confidential;
- what must be shared for safety;
- what summaries teachers may receive;
- how counselling differs from discipline;
- how students can request or decline help, subject to local policy and safeguarding.

Without clarity, students may experience counselling as surveillance and teachers may expect reports the counsellor cannot ethically provide.

## 2. Tiered Support

A multi-tiered system organises support by intensity.

**Tier 1: universal.** Safe climate, belonging, social-emotional learning, anti-bullying systems, mental health literacy, staff training, accessible routines, and student voice.

**Tier 2: targeted.** Small groups, mentoring, brief interventions, attendance support, family check-ins, and skills programmes for students with emerging needs.

**Tier 3: intensive.** Individual counselling, coordinated care, specialist referral, safety planning, and personalised school adjustments.

Tiering should be a route to help, not a queue that requires failure at each level before support increases. Screening and teacher referral must be monitored for bias: quiet internalising students, disabled students, racialised students, LGBTQ+ students, carers, and students whose families distrust services may be identified differently.

## 3. Direct Counselling in Schools

School counselling is often brief, interrupted by timetables, examinations, staff absence, and holidays. Practitioners need focused assessment, clear goals, session-by-session review, and planned endings between terms.

Confidentiality in corridors matters. Appointment slips, room location, teacher messages, and being collected from class can disclose service use. Systems should allow discreet scheduling.

Evidence-informed school work may draw on CBT, behavioural activation, motivational interviewing, solution-focused practice, IPT-A, trauma-informed stabilisation, family consultation, and group interventions. Choice depends on formulation and competence, not simply available time.

## 4. Consultation

Consultation is indirect service: the counsellor helps a teacher, parent, or team change the environment or interaction around a student. It is not giving orders from superior expertise.

A collaborative consultation sequence includes:

1. establish purpose and confidentiality;
2. define the concern in observable terms;
3. gather context and previous responses;
4. consider student perspective and function;
5. generate options;
6. choose small feasible actions;
7. assign responsibilities;
8. review data and revise.

Teacher consultation must respect workload. A plan requiring six adults to perform ten steps perfectly will fail. One change in instruction delivery, seating, feedback privacy, or break access may be more effective.

## 5. Family Collaboration

Families know routines, history, culture, strengths, and barriers invisible at school. Collaboration begins with listening rather than reporting failures. Interpreters, flexible meeting times, remote options, and accessible documents are equity practices.

Where family and school accounts conflict, the counsellor avoids becoming a messenger of blame. Joint meetings need purpose, preparation, student voice, and agreement about what will be recorded.

- Brown, D., & Trusty, J. (2005). *Designing and Leading Comprehensive School Counseling Programs*.

## 7. Crisis and Postvention

School crises include student death, suicide, violence, accidents, community disasters, and public incidents amplified by social media. Counsellors help coordinate factual communication, support for affected groups, identification of vulnerable students, family liaison, staff support, and referral.

Postvention after a suicide requires specialist guidance: avoid glamourising details, monitor contagion risk, support grief, communicate safely, and provide sustained follow-up. Rumours and online material should be addressed without repeating harmful content unnecessarily.

Crisis work also includes returning to ordinary routines. Predictability is regulating. Memorial practices should be inclusive, voluntary, culturally sensitive, and consistent with guidance.

## 8. Safeguarding and Multi-Agency Work

School counsellors often receive disclosures because they are accessible and trusted. They must know local safeguarding procedures, record accurately, avoid investigative interviewing beyond their role, and communicate promptly with designated leads.

Multi-agency work requires consent where possible, clear purpose, minimum necessary information, and attention to the young person's experience of meetings. A student should know who will attend, what will be discussed, and how their views will be represented.

Advocacy may involve special educational needs assessment, disability accommodations, exclusion prevention, alternative provision, housing or benefits referral, health appointments, and protection from bullying or discrimination.

## 9. Behaviour, Attendance, and Belonging

The counsellor's contribution to behaviour and attendance is formulation, not merely consequence delivery. Useful questions include: What skill is missing? What is being avoided or obtained? Where does the behaviour not occur? What adult responses help? What curriculum, sensory, language, health, transport, or peer factors operate?

Restorative approaches can repair harm where participation is voluntary and safety permits. They should not force victims to confront perpetrators or substitute for safeguarding.

Attendance work combines early identification, family partnership, practical barriers, school belonging, health, graded return, and monitoring. Public attendance shaming and purely punitive approaches often deepen avoidance.

## 10. Case Illustration: The Counsellor Who Refused the Report

**Situation.** A head of year asks the counsellor to report whether a fifteen-year-old “admitted” leaving school grounds and to recommend a sanction.

**Response.** The counsellor explains the role boundary: counselling content cannot be converted into disciplinary evidence, except where safeguarding or agreed information sharing applies. The counsellor offers consultation instead: review supervision patterns, reasons students leave at lunch, safe spaces, and a support plan based on information the student agrees to share.

**Consultation.** Data show most departures occur after a crowded lunch period and before double science. The student, consulted separately with consent, identifies noise, hunger due to long queues, and anxiety about entering a lesson late after lunch. The school adjusts lunch access, creates a quieter eating space, and permits direct entry to science for two weeks. The counsellor works individually on panic and planning.

The refusal protects trust while still helping the institution solve its problem.

## 11. Programme Evaluation and Advocacy

School counselling should evaluate:

- access and waiting time;
- student-defined goals and experience;
- symptoms and functioning;
- attendance, participation, and attainment where relevant;
- equity of referral and outcome;
- teacher and family consultation impact;
- crisis response and referral completion.

Data should be reported in aggregate and used to improve systems, not to pressure counsellors into selecting easy cases. Student voice should inform service design, including room location, referral routes, session length, digital access, and confidentiality communication.

Advocacy arises from patterns: repeated bullying in one location, inaccessible homework platforms, exclusion disparities, lack of interpreters, or timetable structures that prevent sleep and eating. The counsellor brings data, student perspective, and feasible proposals to leadership.

## 12. Ethics and Professional Identity

School counsellors manage dual loyalties to student, family, school, profession, and law. Written role statements, supervision external to line management where possible, record separation, and clear information-sharing agreements reduce conflict.

Counsellors should not conduct therapy with students they also discipline, grade, or investigate. Where small schools make overlap unavoidable, disclose limits and seek supervision and alternative referral options.

Caseload and time must permit safeguarding and crisis duties. A service measured only by number of sessions may neglect prevention and consultation where population impact is greater.

## 13. Key Terms

**Key Terms at a Glance**

- **Consultation** — Collaborative indirect service that helps adults alter environments or interactions around a young person.
- **Tiered support** — Organisation of universal, targeted, and intensive interventions.
- **Postvention** — Coordinated support after a death or crisis to reduce harm and support recovery.
- **Role clarity** — Explicit definition of the counsellor's functions, limits, and information-sharing practices.
- **Student voice** — Meaningful participation of students in decisions and service evaluation.
- **Restorative practice** — Voluntary processes focused on understanding harm, accountability, and repair.

## 14. Chapter Summary

School counselling is both intimate and institutional. It protects a confidential relationship while changing classrooms, corridors, policies, and partnerships around the student. Its credibility depends on refusing incompatible roles, consulting collaboratively, and using evidence to advocate for environments in which fewer students need rescue.

## 15. Review and Discussion Questions

**Review and Discussion Questions**

1. Distinguish counselling, consultation, prevention, coordination, and advocacy in a school.
2. Why should counselling not function as discipline?
3. Design a three-tier response to exam anxiety.
4. Write a confidentiality explanation suitable for a thirteen-year-old and their teacher.
5. Apply the eight-step consultation sequence to repeated classroom exit.
6. What data would reveal inequitable access to school counselling?
7. How should a counsellor respond to a request for session content to support a sanction?

## 16. Practice Activities

**Practice and Application**

### Activity 56.1 — Role statement

Draft a 200-word school counselling role statement for a student handbook.

### Activity 56.2 — Consultation plan

Use the collaborative sequence to address a student who leaves one teacher's lessons but not others.

### Activity 56.3 — Tier map

Map a school's response to bullying across universal, targeted, and intensive levels.

## 17. Annotated Reading Pathways

**For comprehensive programmes.** The ASCA model is influential but should be adapted to local governance and professional standards.

**For ethics.** Stone's work is valuable on confidentiality, records, court involvement, and school-specific dilemmas.

**For practice.** Combine school counselling texts with implementation science, special education, attendance research, and child safeguarding guidance.

## Practice Laboratory and Extended Worked Example

This laboratory turns **School Counseling Practice and Consultation** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is the school counselor's role, the consultation model, and the ethics of working in an institutional setting. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The mechanism to keep in view is how assessment becomes a sequenced, reviewable plan whose parts are matched to mechanisms, people, settings, and evidence. The characteristic professional risk is collecting techniques without coherence, exceeding competence, or allowing documentation and institutional targets to replace the young person's goals. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | “I know what this is and what may be shared.” | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | “Adults are not treating one setting as my whole life.” | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | “The problem has a pattern; I am not simply the problem.” | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | “This account fits, partly fits, or needs changing.” | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | “These goals are mine as well as the service's.” | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | “I have a way to begin, not just an instruction.” | Observed practice, mastery, and confidence ratings. |

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 7. Apply the method | Use the chapter's core procedures in case conferences, supervision, school and clinic teams, teaching sessions, and service review, adapting dose and pace to development and state. | “The work is challenging but understandable and stoppable.” | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | “This is not only something I do in a counselling room.” | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | “A setback leads to inquiry, not blame.” | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | “Adults are changing some conditions too.” | Meeting actions, school adjustments, and referral outcomes. |
| 11. Cons olidate | Name the strategies, relationships, and environmental changes that produced improvement. | “I can explain what helps and why.” | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | “Ending is planned; I am not disappearing from care.” | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support,

timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Marcus is fifteen and is seen in a community adolescent clinic for school avoidance and rising panic. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Marcus's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Marcus explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The first intervention is deliberately modest. Marcus chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Marcus has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Marcus can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point

at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for School Counseling Practice and Consultation

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **School Counseling Practice and Consultation** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

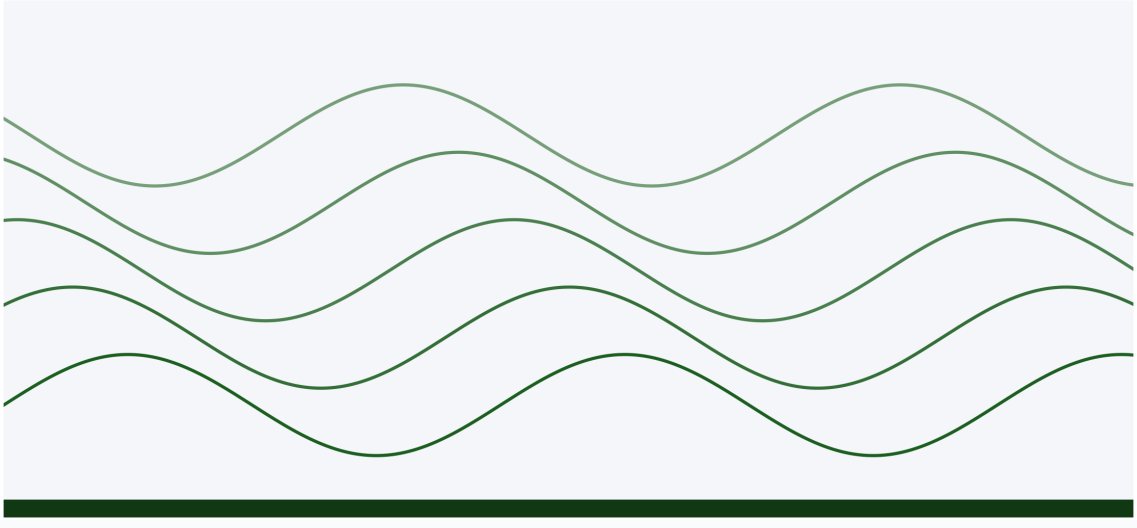
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **School Counseling Practice and Consultation** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **School Counseling Practice and Consultation**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into



clinical governance.

**Written consolidation.** In 250 words, explain School Counseling Practice and Consultation to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 57

# Teaching CAC. 701: Session Plans and Facilitation

A complete teaching sequence for the course, including delivery notes, activities, and assessment alignment.

## Learning Objectives

By the end of this chapter, the lecturer should be able to:

- Translate the CAC. 701 syllabus into a coherent sixteen-week teaching sequence.
- Construct session plans with outcomes, preparation, teaching activities, assessment, and resources.
- Facilitate discussion of counselling theory without reducing it to memorisation.
- Use case vignettes, role play, observation, writing, and digital resources safely.
- Support students with varied academic, linguistic, disability, and professional backgrounds.
- Assess participation and contribution without rewarding disclosure of personal trauma.
- Evaluate and revise teaching using student feedback and assessment evidence.

## Chapter Overview

Teaching counselling theories is not the delivery of a museum of famous names. Students must learn to think with theories: to notice what a theory sees, what it misses, how it explains change, what interventions follow, what evidence supports it, whom it fits, and where it may harm. A CAC. 701 session should therefore alternate explanation, demonstration, comparison, practice, critique, and reflection.

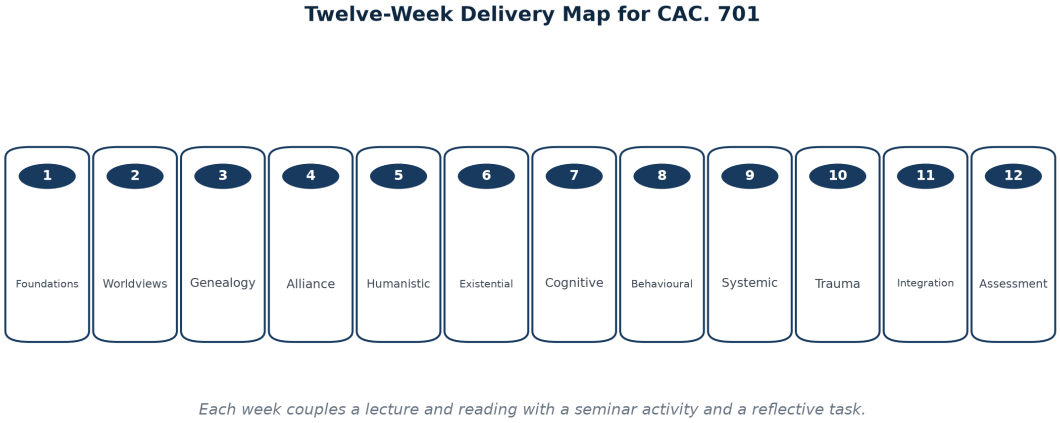


**Figure 57.49** A course map for CAC. 701 linking foundational concepts, major theory families, youth applications, integration, assessment, and professional practice.

This chapter offers a teaching architecture rather than a script. Lecturers should adapt examples, pacing, readings, and assessments to institutional requirements and student needs while preserving constructive alignment: outcomes, activities, and assessment must point in the same direction.

## 1. Course Design Principles

**Start with clinical problems.** Students remember theories better when each is introduced through a human situation. Begin with a brief vignette, ask what needs explaining, then present the theory as one disciplined way of seeing.

**Compare early and often.** Comparison prevents brand loyalty. Ask how behavioural, cognitive, humanistic, family, trauma-informed, and cultural accounts differ in cause, change, role of counsellor, and evidence.

**Teach evidence with concepts.** A theory should not be presented first as timeless truth and later as research topic. Include evidence, limitations, and populations studied as part of the theory's identity.

**Practise safely.** Skills laboratories require consent, alternatives to personal disclosure, clear roles, stop rules, and debriefing. Students should practise on fictional or consented material, not be required to reveal trauma to pass.

**Make youth central.** Every adult-origin theory must be interrogated for developmental fit: cognition, language, autonomy, family dependence, school context, consent, and power.

**Model cultural humility.** Teaching examples should vary across family forms, languages, disability, class, migration, gender, sexuality, and community contexts without turning any group into a spectacle.

## 2. Sixteen-Week Sequence

A possible sequence is:

1. Why theory matters; course map; formulation as disciplined seeing.
2. Scientific, philosophical, and professional foundations.
3. Worldviews, common factors, alliance, and evidence appraisal.
4. Developmental and cultural foundations for youth counselling.
5. Person-centred, existential, Gestalt, and focusing approaches.
6. Transactional analysis, internal family systems, and parts language.
7. Cognitive model, REBT, schema concepts, and youth CBT.
8. ACT, DBT skills, mindfulness, and third-wave debates.
9. Behavioural principles, functional assessment, exposure, and contingencies.
10. Behavioural activation, school and clinic systems.
11. Family systems: Bowen, structural, and strategic approaches.
12. Attachment, solution-focused, and narrative practice.
13. Emotion-focused, trauma-informed, EMDR, stabilisation, and somatic practice.
14. IPT-A, mentalization, motivational interviewing, and social cognitive theory.
15. Adolescent development, psychodynamic, multicultural, feminist, intersectional, LGBTQ+ affirmative, resilience, and ecological practice.
16. Integration, case conceptualisation, assessment, ethics of endings, teletherapy, school consultation, and capstone formulation.

This sequence compresses substantial material in later weeks. Institutions with more time may divide weeks 14–16 into separate units. The logic is cumulative: foundations, relationship, major mechanisms, systems, development and culture, then integration and professional use.

## 3. Anatomy of a Three-Hour Session

A three-hour postgraduate session might use the following rhythm:

**Opening and retrieval (15 minutes).** A low-stakes question connecting to the previous week.

**Clinical problem (15 minutes).** A short case vignette read aloud or shown in text; students identify what needs explanation.

**Concept teaching (35 minutes).** Core theory, key terms, mechanisms, and a diagram.

**Demonstration (25 minutes).** Lecturer demonstration, recorded session excerpt with permission, transcript analysis, or live structured role play.

**Break (10 minutes).**

**Application laboratory (40 minutes).** Triads practise with fictional material; observer uses a structured feedback form.

**Evidence and critique (20 minutes).** Trial or review summary, limitations, cultural questions, populations missing.

**Formulation synthesis (15 minutes).** Students write what the theory changes in a treatment plan.

**Exit assessment (5 minutes).** One concept learned, one question remaining, one application to youth practice.

Not every week needs every element. Predictable rhythm reduces anxiety, while variation in tasks maintains attention.

## 4. Facilitation Moves

Useful lecturer moves include:

- asking for observations before interpretations;
- inviting competing theoretical readings of the same event;
- writing student language verbatim before translating into theory;
- pausing after questions long enough for thought;
- asking who benefits and who may be harmed by an intervention;
- distinguishing evidence, clinical tradition, and personal preference;
- summarising disagreement accurately;
- returning to the young person's voice.

Lecturers should avoid rewarding the most confident speaker as the most competent thinker. Written responses, pairs, anonymous digital polls, and small groups distribute participation.

## 5. Further Reading for This Chapter

- Fink, L. D. (2013). *Creating Significant Learning Experiences* (2nd ed.).

- Ambrose, S. A., et al. (2010). *How Learning Works*.
- Nilson, L. B. (2016). *Teaching at Its Best* (4th ed.).

# 6. Session Plans for Selected Units

## Session A: Functional assessment

**Outcomes.** Students can operationalise a behaviour, generate at least three functional hypotheses, and identify data that would discriminate among them.

**Preparation.** Read Chapters 24 and 26; bring an anonymised ABC observation from practice or use the provided fictional record.

**Activities.** Ten-minute concept review; lecturer models faulty versus testable hypotheses; groups analyse a school incident log; each group designs one observation and one intervention; plenary compares ethical safeguards.

**Assessment.** Exit ticket requiring one operational definition and one disconfirming observation.

## Session B: Family systems

**Outcomes.** Students can draw a structural map, identify triangles, and separate structural from interactional formulation.

**Preparation.** Read Chapters 30–33.

**Activities.** Case reading; small-group mapping; lecturer-led comparison of Bowenian, structural, and strategic plans; practice a family opening statement; critique cultural assumptions.

**Assessment.** Short formative map submitted for feedback, not grading of artistic quality.

## Session C: Trauma-informed practice

**Outcomes.** Students can identify state, phase, safety requirements, and inappropriate timing of trauma processing.

**Preparation.** Read Chapters 38 and 40.

**Activities.** State-recognition exercise using fictional transcripts; phase placement; grounding demonstration with opt-out; design a school environment audit; discuss the difference between trauma-informed care and trauma-specific treatment.

**Assessment.** Written phase justification with criteria for moving forward and backward.

## Session D: Integration capstone

**Outcomes.** Students can produce a coherent, sequenced, culturally responsive plan and defend omissions as well as inclusions.

**Activities.** Complex case distributed in stages; groups revise formulation as new information arrives; cross-group peer review; lecturer models supervision questions.

**Assessment.** Draft capstone formulation for formative feedback before final submission.

## 7. Role Play and Demonstration Ethics

Role play is a laboratory, not group therapy. The lecturer must:

- use fictional cases by default;
- obtain consent for roles and recording;
- permit observer or writer roles;
- set stop signals;
- prohibit use of classmates' real trauma;
- debrief role occupants out of character;
- give feedback on observable skills, not personality;
- provide alternatives for students for whom a scenario is personally activating.

Demonstrations should be interrupted for teaching points rather than performed as virtuoso displays. If a demonstration fails, analyse it. Students learn more from repair than perfection.

## 8. Inclusive Teaching

Accessibility begins before requests. Provide slides and readings in accessible formats, caption videos, describe diagrams, allow assistive technology, avoid colour-only meaning, and state assessment criteria plainly. Offer multiple ways to participate: speech, writing, anonymous response, small group, and asynchronous forum.

Language support includes glossaries, pre-reading questions, and permission to discuss concepts in a stronger language before presenting in academic English where institutional rules permit. International students should not be treated as deficits when their experience exposes the cultural limits of a theory.

Attendance flexibility must balance professional formation with disability, caring, work, health, and transport realities. Participation grades based solely on speaking frequency are inequitable.

## 9. Difficult Classroom Moments

Students may disclose personal trauma, challenge a theory on cultural grounds, defend a prohibited practice, disclose risk, or become distressed. The lecturer should acknowledge, protect privacy, avoid turning disclosure into teaching spectacle, and follow safeguarding routes.

Disagreement is valuable. Distinguish critique of ideas from attacks on people. Ask speakers to identify evidence and implications. Where discussion involves identities represented in the room, do not appoint any student as spokesperson for a group.

Assessment integrity requires clear policy on collaboration, generative AI, plagiarism, and use of client material. Students must anonymise practice examples and never submit identifiable client information.

## 10. Evaluating Teaching

Evaluation should combine student feedback, peer observation, assessment patterns, and lecturer reflection. If many students confuse two concepts, teaching may need restructuring rather than students simply being

told to study harder.

Track whether case examples remain diverse, whether skills practice produces competence, whether feedback is timely, and whether assessment tasks align with outcomes. Revise one or two elements at a time so changes can be understood.

## 11. Key Terms

**Key Terms at a Glance**

- **Constructive alignment** — Coherence among outcomes, learning activities, and assessment.
- **Formative assessment** — Assessment used to guide learning before final judgement.
- **Retrieval practice** — Actively recalling prior learning to strengthen understanding.
- **Skills laboratory** — Structured practice with fictional material, observation, feedback, and debriefing.
- **Inclusive teaching** — Design that anticipates varied access, language, disability, and participation needs.
- **Capstone formulation** — A culminating case conceptualisation integrating theory, development, culture, evidence, and planning.

## 12. Chapter Summary

Teaching CAC. 701 is itself an exercise in formulation. The lecturer identifies what students need to notice, designs experiences that make theory usable, observes misunderstanding without shame, and revises. A successful course does not produce loyalty to one school. It produces practitioners who can explain their choices, recognise limits, and keep the young person—not the theory—at the centre.

## 13. Review and Discussion Questions

**Review and Discussion Questions**

1. Why should theory teaching begin with clinical problems?
2. Design a three-hour session on exposure that includes evidence and ethics.
3. What safeguards distinguish a skills laboratory from group therapy?
4. How can participation be assessed equitably?
5. Identify one point where a lecturer's preferred theory could bias teaching.
6. What student assessment evidence would lead you to revise a session?
7. Explain constructive alignment using the functional assessment session plan.

## 14. Practice Activities

**Practice and Application**

### Activity 57.1 — Session design

Create a 90-minute session plan for narrative therapy with outcomes, preparation, activities, assessment, and accessibility notes.

### Activity 57.2 — Demonstration debrief

Write a debrief script for a role play in which the “counsellor” accidentally pressures a student actor to disclose.

### Activity 57.3 — Alignment audit

Take one course outcome and trace it through readings, activities, formative work, and final assessment. Identify any break in alignment.

## 15. Annotated Reading Pathways

**For course design.** Biggs and Tang and Fink help align outcomes, activities, and assessment.

**For facilitation.** Brookfield supports critical reflection on power and student perception.

**For learning science.** Ambrose and colleagues provide practical principles on prior knowledge, organisation, motivation, feedback, and self-directed learning.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Teaching CAC. 701: Session Plans and Facilitation** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is a complete teaching sequence for the course, including delivery notes, activities, and assessment alignment. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The mechanism to keep in view is how assessment becomes a sequenced, reviewable plan whose parts are matched to mechanisms, people, settings, and evidence. The characteristic professional risk is collecting techniques without coherence, exceeding competence, or allowing documentation and institutional targets to replace the young person's goals. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements;

others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | "I know what this is and what may be shared." | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | "Adults are not treating one setting as my whole life." | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | "The problem has a pattern; I am not simply the problem." | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | "This account fits, partly fits, or needs changing." | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | "These goals are mine as well as the service's." | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | "I have a way to begin, not just an instruction." | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in case conferences, supervision, school and clinic teams, teaching sessions, and service review, adapting dose and pace to development and state. | "The work is challenging but understandable and stoppable." | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | "This is not only something I do in a counselling room." | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | "A setback leads to inquiry, not blame." | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | "Adults are changing some conditions too." | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | "I can explain what helps and why." | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | "Ending is planned; I am not disappearing from care." | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable, and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Leah is fifteen and is seen in a family support service for repeated classroom escalation. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Leah's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner

first establishes safety, consent, and context. Leah explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home, concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The first intervention is deliberately modest. Leah chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Leah has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Leah can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.

- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.
- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Teaching CAC. 701: Session Plans and Facilitation

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Teaching CAC. 701: Session Plans and Facilitation** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

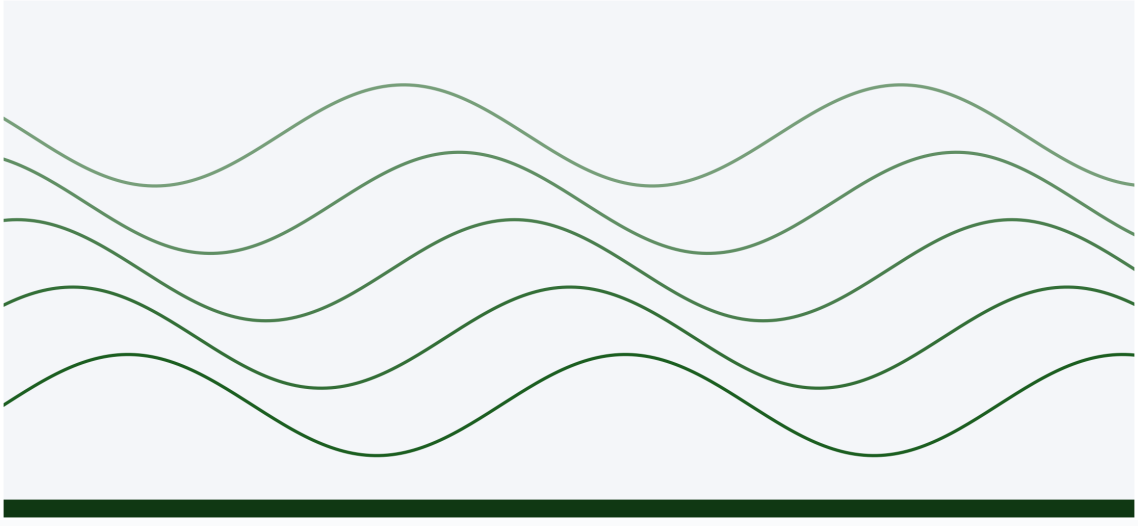
**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's

goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Teaching CAC. 701: Session Plans and Facilitation** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.



**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Teaching CAC. 701: Session Plans and Facilitation**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Teaching CAC. 701: Session Plans and Facilitation to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER 58

# Assessment Blueprint, Assignments, and Rubrics

Course-level assessment design, major assignments, grading rubrics, and the assurance of academic integrity.

## Learning Objectives

By the end of this chapter, the student and lecturer should be able to:

- Map CAC. 701 assessments to course outcomes and programme expectations.
- Design valid, reliable, fair, and feasible assignments for theory learning.
- Write transparent marking criteria and rubrics.
- Assess case conceptualisation, evidence appraisal, skills demonstration, reflection, and professional judgement.
- Provide feedback that students can use in subsequent work.
- Apply academic integrity, accessibility, moderation, and appeals principles.
- Use assessment data to improve teaching and demonstrate course quality.

## Chapter Overview

Assessment tells students what the course truly values. If lectures praise cultural humility, developmental reasoning, and client voice but examinations reward only memorised names and dates, students will memorise names and dates. The CAC. 701 blueprint therefore assesses theory as professional capability: seeing, formulating, choosing, justifying, practising, evaluating, and revising.

**Course Assessment Blueprint for CAC. 701**

| Learning outcome | Teaching activity | Assessment evidence | Weight |
|---|---|---|---|
| Explain and compare major theories | Lectures, seminar comparison tables | Theory comparison paper | 20% |
| Apply theory to a child or adolescent case | Case formulation seminar | Formulation assignment | 25% |
| Evaluate the evidence for a model | Critical reading seminar | Annotated bibliography | 15% |
| Demonstrate core counselling skills | Role-play and skills laboratory | Skills demonstration | 15% |
| Reflect on ethical and cultural practice | Ethics case clinic | Reflective journal and viva | 15% |
| Design an evidence-based treatment plan | Planning workshop | Treatment plan submission | 10% |

*Every assessment task maps to a stated learning outcome and to at least one course objective.*

**Figure 58.50** An assessment blueprint mapping outcomes to essays, case formulation, evidence appraisal, skills practice, reflection, and examination.

## 1. Blueprint Principles

A defensible blueprint states:

- course learning outcomes;
- programme and professional competencies addressed;
- assessment tasks and weighting;

- timing and formative preparation;
- criteria and standards;
- moderation and feedback arrangements;
- accessibility and integrity requirements.

Validity asks whether the task measures the intended capability. Reliability asks whether judgements are consistent. Fairness asks whether irrelevant factors—handwriting, accent, confidence, cultural style, disability, technology access—distort performance. Feasibility asks whether students and markers can complete the work to the stated standard.

No single task can assess everything well. The course therefore combines written analysis, case formulation, evidence appraisal, observed practice, reflective commentary, and invigilated or time-bound synthesis where required by institutional rules.

## 2. Proposed Assessment Pattern

Subject to institutional approval, a balanced pattern is:

| Assessment | Weight | Primary capability |
|---|---|---|
| Theory comparison essay | 20% | Conceptual understanding and critical comparison |
| Evidence appraisal brief | 15% | Research literacy and application to youth |
| Case conceptualisation and treatment plan | 30% | Integrative formulation and planning |
| Observed skills practice with rationale | 20% | Theory-informed intervention and reflection |
| Professional learning portfolio | 15% | Development, ethics, culture, and self-assessment |

A final examination may replace or supplement one component where regulations require. If used, examination questions should require application to unseen cases, not only recall.

## 3. Assignment One: Theory Comparison Essay

**Task.** Compare two theories in relation to adolescent anxiety, depression, school refusal, family conflict, trauma, or another approved presentation. Address view of the person, causation, change, counsellor role, techniques, development, culture, evidence, limitations, and suitability.

**What excellence looks like.** The essay goes beyond parallel summaries. It identifies genuine points of commensurability and conflict, uses evidence accurately, considers a concrete adolescent example, and reaches a justified conclusion.

**Common weaknesses.** Biography replacing analysis; listing techniques without mechanisms; treating evidence as vote counting; assuming adult findings transfer unchanged to adolescents; ignoring family, school, and culture.

## 4. Assignment Two: Evidence Appraisal Brief

**Task.** Select a research article, systematic review, or clinical guideline relevant to one theory or intervention. Appraise question, design, sample, measures, analysis, effect size, limitations, applicability, and implications for youth practice in no more than the assigned length.

Students should distinguish statistical significance from clinical importance and efficacy under trial conditions from effectiveness in ordinary services. They should identify who was excluded from the study and what the intervention required in staffing, training, and time.

A short recommendation section must state: use, adapt, use with caution, or do not use—plus what outcome would be monitored locally.

## 5. Assignment Three: Case Conceptualisation and Treatment Plan

**Task.** Using a provided complex case, produce a developmental, cultural, relational, and evidence-informed formulation and a sequenced treatment plan.

The submission includes:

1. presenting summary and risk;
2. five-part formulation;
3. theory-informed explanation using at least three lenses without incoherent mixing;
4. goals negotiated from client, family, and service perspectives;
5. sequenced interventions with rationale and responsibilities;
6. school, family, health, and safeguarding coordination;
7. outcome measures and review criteria;
8. ethical and cultural analysis;
9. criteria for referral, intensification, or ending.

Word limits reward prioritisation. Appendices may include diagrams and measures but cannot be used to evade core analysis.

## 6. Further Reading for This Chapter

- Biggs, J., & Tang, C. (2011). *Teaching for Quality Learning at University* (4th ed.).
- Race, P. (2020). *Making Learning Happen* (4th ed.).
- Rust, C. (2002). The impact of assessment on student learning. *Active Learning in Higher Education, 3*(2), 145–158.
- Sadler, D. R. (1989). Formative assessment and the design of instructional systems. *Instructional Science, 18*, 119–144.
- Hattie, J., & Timperley, H. (2007). The power of feedback. *Review of Educational Research, 77*(1), 81–112.

## 7. Assignment Four: Observed Skills Practice

**Task.** In a structured practice with a fictional adolescent or family scenario, demonstrate a theory-informed intervention segment and submit a written rationale and reflection.

Assessment focuses on:

- contracting, consent, and safety;
- relationship and listening;
- accurate use of theory-linked skills;
- developmental and cultural responsiveness;
- pacing, boundaries, and response to emotion;
- avoiding harm, coercion, and inappropriate disclosure;
- recognising what did not work;
- identifying next steps.

Students are not assessed on producing a miraculous outcome in fifteen minutes. They are assessed on judgement, process, ethics, and learning. Alternative formats should be available where disability, language, or other access needs require, while preserving the capability being assessed.

## 8. Assignment Five: Professional Learning Portfolio

The portfolio may include:

- a revised formulation showing how feedback changed thinking;
- a cultural humility reflection linked to concrete practice decisions;
- an evidence summary used in teaching or placement;
- a supervision or peer feedback response;
- an ethics analysis;
- a personal development plan with limits of competence.

Reflection should not be graded by amount of personal disclosure. Students may analyse fictional or anonymised material. The criterion is quality of reasoning, connection to evidence and professional standards, and specificity of future action.

## 9. Rubric for Case Conceptualisation

| Criterion | Excellent | Proficient | Developing | Insufficient |
|---|---|---|---|---|
| Formulation | Integrated, developmental, cultural, concise, and testable | Coherent with most relevant factors | Descriptive or partly list-like | Retells case or relies on diagnosis alone |
| Theory use | Theories are compared, sequenced, and linked to mechanisms | Theories are applied accurately | Theory named but weakly linked | Techniques are listed without rationale |

| Criterion | Excellent | Proficient | Developing | Insufficient |
|---|---|---|---|---|
| Planning | Prioritised, feasible, collaborative, and safety-aware | Clear goals and interventions | Generic or overloaded plan | Unsafe, impractical, or missing plan |
| Evidence | Current, critically appraised, youth-relevant | Relevant evidence used accurately | Evidence mentioned superficially | Unsupported claims or adult evidence assumed transferable |
| Ethics and culture | Power, consent, equity, and context shape decisions | Main ethical and cultural issues addressed | Generic statements | Issues ignored or stereotyped |
| Evaluation | Measures, review points, and change criteria are explicit | Outcomes identified | Vague intention to review | No evaluation |
| Communication | Clear, respectful, professional, well organised | Generally clear | Difficult to follow in places | Incoherent or disrespectful language |

Rubrics guide judgement; they do not replace it. Borderline and failing work should receive marker comments tied to criteria and, where institutional rules require, second marking or moderation.

## 10. Rubric for Observed Practice

| Criterion | Indicators of strong performance |
|---|---|
| Contracting | Purpose, confidentiality limits, consent, time, and choices are clear |
| Relationship | Warmth, attention, pacing, and respect are sustained without over-familiarity |
| Theory application | Interventions follow from a stated model and are adapted in real time |
| Developmental fit | Language, autonomy, family context, and capacity are appropriately addressed |
| Cultural responsiveness | Assumptions are checked; identity and power are handled respectfully |
| Safety | Emotion, risk cues, boundaries, and stopping points are managed responsibly |
| Reflection | Student identifies strengths, errors, alternatives, and supervision questions accurately |

A serious ethical breach—such as coercing disclosure, inventing confidentiality promises, or ignoring expressed withdrawal of assent—cannot be offset by fluent technique and should be handled under institutional fitness-to-practise procedures where applicable.

## 11. Feedback, Moderation, and Integrity

Feedback should identify what met the standard, what did not, why it matters, and what to do next. It should arrive while students can still use it. Audio or annotated feedback may help, provided accessibility and records are managed.

Moderation includes calibration meetings, sample second marking, review of grade distributions, external examining where applicable, and analysis of differential outcomes. Markers should discuss anonymised

examples before assessing high-stakes work.

Integrity rules must address plagiarism, contract cheating, unauthorised collaboration, fabricated practice evidence, misuse of client data, and generative AI. Policies should distinguish permitted study support from submitting generated work as one's own analysis. Students should declare assistance where required and remain accountable for accuracy, confidentiality, and reasoning.

No identifiable client material may be placed into external AI systems or public platforms. Even anonymised cases can be identifiable in small communities; institutional guidance governs.

## 12. Accessibility and Fairness

Assessment design should provide clear instructions, examples of structure without model answers that invite copying, reading lists in accessible formats, and reasonable adjustments. Extra time, assistive technology, alternative oral or written formats, and adjusted practice settings should preserve the assessed capability while removing irrelevant barriers.

Group work requires individual accountability and processes for conflict, unequal labour, caring responsibilities, and accessibility. Peer assessment should be formative unless carefully moderated.

Students should have access to criteria before submission, formative opportunities, academic skills support, and transparent late submission, extension, resubmission, and appeals procedures.

## 13. Using Assessment Data

Course teams should review:

- outcome-level performance patterns;
- marker consistency;
- differential attainment and access;
- student feedback and workload;
- skills that remain weak across cohorts;
- whether cases and examples reflect diverse youth contexts;
- whether graduates can transfer theory into practice.

Changes should be documented in course review. If students perform well on essays but poorly in formulation, teaching needs more worked examples and formative case practice. If skills are technically fluent but ethically weak, laboratory supervision and criteria require attention.

## 14. Key Terms

**Key Terms at a Glance**

- **Assessment blueprint** — A map linking outcomes, tasks, weighting, criteria, and quality assurance.
- **Validity** — The extent to which assessment supports intended interpretations and decisions.
- **Reliability** — Consistency of assessment judgements.
- **Moderation** — Processes that calibrate and verify marking standards.
- **Constructive alignment** — Coherence among outcomes, learning activities, and assessment.
- **Fitness to practise** — Professional suitability requirements concerning safety, conduct, and competence.

## 15. Chapter Summary

The assessment system for CAC. 701 should model the counselling it teaches: clear contracting, developmental sensitivity, cultural fairness, evidence-informed judgement, useful feedback, ethical boundaries, and review. Students pass not by sounding like theorists, but by demonstrating that they can use theory to help a young person safely, coherently, and accountably.

## 16. Review and Discussion Questions

**Review and Discussion Questions**

1. Why does assessment reveal a course's real values?
2. Evaluate the proposed weighting for CAC. 701. What would you change and why?
3. Distinguish validity, reliability, fairness, and feasibility.
4. Why should observed practice not be graded mainly on client outcome?
5. What portfolio evidence shows learning without requiring personal disclosure?
6. How should generative AI be addressed in assessment policy?
7. Use rubric data to propose one course improvement.

## 17. Practice Activities

**Practice and Application**

### Activity 58.1 — Blueprint audit

Map an existing course assessment to outcomes and identify unassessed or over-assessed capabilities.

### Activity 58.2 — Marker calibration

Write feedback for a borderline case formulation using the rubric, then compare priorities with a peer.

### Activity 58.3 — Feedback rewrite

Rewrite “Good effort, needs more theory” into feedback identifying standard, evidence, impact, and next action.

## 18. Annotated Reading Pathways

**For assessment design.** Biggs and Tang provide constructive alignment; Sadler and Hattie explain feedback that changes learning.

**For rubrics.** Use rubrics with exemplars, calibration, and narrative comments. A grid without marker judgement creates false precision.

**For integrity and accessibility.** Follow current institutional policy and professional standards, especially where practice material, disability adjustments, and digital tools are involved.

## Practice Laboratory and Extended Worked Example

This laboratory turns **Assessment Blueprint, Assignments, and Rubrics** into decisions that can be observed, supervised, and reviewed. The chapter's central concern is course-level assessment design, major assignments, grading rubrics, and the assurance of academic integrity. In adolescent work, understanding the model is only the first step. The practitioner must also decide what to assess, what to postpone, which adults or institutions need to act, how consent will be maintained, and what evidence would show that the work is helping rather than merely continuing. The organising focus for this part of the course is integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The mechanism to keep in view is how assessment becomes a sequenced, reviewable plan whose parts are matched to mechanisms, people, settings, and evidence. The characteristic professional risk is collecting techniques without coherence, exceeding competence, or allowing documentation and institutional targets to replace the young person's goals. Keep those three sentences available during case discussion. They prevent a common form of drift in which a practitioner uses familiar language from a theory while the actual session is being governed by urgency, institutional pressure, or the wish to make distress stop quickly.

### A twelve-part application map

The following map is not a rigid manual. It is a way of checking whether the work has a beginning, a middle, a reviewable middle-late phase, and an ending. Some young people need only selected elements; others require a much longer stabilisation period or referral before the central method is appropriate.

| Phase | Practitioner task | Young person's experience | Evidence to review |
|---|---|---|---|
| 1. Contract | Explain purpose, confidentiality limits, choices, session rhythm, and complaint or advocacy routes. | "I know what this is and what may be shared." | Consent/assent record and the young person's own summary. |
| 2. Map contexts | Gather home, school, peer, digital, health, cultural, and material contexts relevant to the referral. | "Adults are not treating one setting as my whole life." | A context map with missing information identified. |
| 3. Identify patterns | Describe sequences, triggers, responses, consequences, strengths, and exceptions in observable language. | "The problem has a pattern; I am not simply the problem." | Baseline notes, diaries, measures, or functional records. |
| 4. Share formulation | Offer a tentative explanation in plain language and invite correction from the young person and, where appropriate, family. | "This account fits, partly fits, or needs changing." | A dated formulation with disagreements recorded. |
| 5. Agree targets | Select a small number of meaningful, feasible, and reviewable goals. | "These goals are mine as well as the service's." | Goal ratings and functional outcomes. |
| 6. Build capacity | Teach, rehearse, model, or arrange the relational and environmental supports required before demanding change. | "I have a way to begin, not just an instruction." | Observed practice, mastery, and confidence ratings. |
| 7. Apply the method | Use the chapter's core procedures in case conferences, supervision, school and clinic teams, teaching sessions, and service review, adapting dose and pace to development and state. | "The work is challenging but understandable and stoppable." | Session records, fidelity notes, and client feedback. |
| 8. Transfer to real life | Plan practice in the settings where change must survive, with adults and peers given clear, limited roles. | "This is not only something I do in a counselling room." | Home, school, or community evidence of generalisation. |
| 9. Review obstacles | Treat non-completion, rupture, or deterioration as information about fit, sequencing, context, or risk. | "A setback leads to inquiry, not blame." | Revised formulation and documented changes. |
| 10. Involve systems | Use consultation, advocacy, family work, or care coordination where the maintaining conditions lie outside the individual session. | "Adults are changing some conditions too." | Meeting actions, school adjustments, and referral outcomes. |
| 11. Consolidate | Name the strategies, relationships, and environmental changes that produced improvement. | "I can explain what helps and why." | Relapse or setback plan in the young person's language. |
| 12. End or transfer | Review gains, unfinished needs, future help routes, and information transfer with consent. | "Ending is planned; I am not disappearing from care." | Closing summary, measures, and follow-up arrangements. |

## Session-by-session guide

**Session one: make the work intelligible.** Begin with the young person's account before offering the theory. Ask what they have been told about the referral, what they expect, what would make sessions unbearable,

and what a useful change would look like in an ordinary week. Explain confidentiality in concrete categories: what remains in counselling, what may be summarised for agreed support, and what may need to be shared for safety. End by checking the explanation back in the young person's words. A technically correct contract that the young person cannot repeat has not yet been understood. **Session two: widen the lens without losing focus.** Map the problem across settings. A difficulty that appears only under public evaluation differs from one that follows the young person everywhere. Record sleep, health, learning, language, family routines, peer contact, digital pressures, and previous help. Ask what adults currently do that helps even slightly, and what they do with good intentions that accidentally maintains the pattern. This session should produce questions, not premature certainty. **Session three: build a shared formulation.** Offer no more than three linked mechanisms at first. For example: a trigger, an interpretation or bodily response, a protective action, and a consequence that brings short-term relief but longer-term cost. Draw the sequence together. Ask the young person to rename any professional term that feels wrong. If parents or school staff will receive a version, agree its content and purpose. The formulation is a working map, not a verdict. **Session four: choose the first experiment.** Select a step small enough to be attempted before the next meeting and important enough to matter. Define who will do what, where, for how long, and how the result will be noticed. Rehearse in session if the step is interpersonal. Predict obstacles without treating them as excuses. A young person who cannot attempt the step has provided information about grading, support, timing, or goal ownership. **Sessions five and six: practise, review, and adjust.** Review actual attempts before introducing new material. What happened first, what followed, and what was learned? Strengthen successful components and revise those that depended on unrealistic adult consistency. If family or school responses undermined the plan, do not solve the problem by asking the young person to try harder inside unchanged conditions. Use consultation or a joint meeting with a narrow purpose. **Sessions seven and eight: deepen without flooding.** By this stage the practitioner may work more directly with emotion, memory, belief, family sequence, behaviour, identity, or relationships, depending on the model. Deepening does not mean intensity for its own sake. Watch arousal, dissociation, shame, and post-session functioning. A session that produces dramatic disclosure followed by school absence, family conflict, or increased self-harm requires reformulation and possibly a slower phase. **Sessions nine and ten: generalise and distribute support.** Move the work into ordinary life. Identify which teacher, parent, carer, mentor, coach, peer, or community adult can support the new pattern without becoming a therapist. Keep instructions brief and observable. The young person should know exactly what information those adults hold. Generalisation fails when every adult improvises a different version of the plan. **Final sessions: consolidate authorship and plan for setbacks.** Review the original goals and the evidence of change. Ask the young person to explain, in their own words, what the problem does, what helps, what early signs matter, and what they will do first if it returns.Practise a likely setback rather than treating relapse as failure. Close with a summary that the young person has seen, a clear route back to help, and transfer of relevant supports to family, school, or community systems.

## Worked example for seminar discussion

Tobias is fifteen and is seen in an integrated school and health team for difficulty trusting adults after several service changes. The referral describes the problem in institutional language and recommends that counselling should improve motivation. Tobias's own first statement is different: “Adults keep asking what is wrong with me, but nobody asks what happens just before it goes wrong.” That sentence becomes the assessment task. The practitioner first establishes safety, consent, and context. Tobias explains that the difficulty is worst when tired, observed by peers, and uncertain about what an adult expects. At home,

concern is expressed through repeated questioning; at school, public correction increases urgency. A previous professional focused only on the visible behaviour and recommended consequences. The new formulation instead asks how state, interpretation, relationships, and consequences interact, consistent with this chapter's focus on integration, formulation, planning, measurement, coordination, ethics, and professional judgement. The first intervention is deliberately modest. Tobias chooses one setting in which to test a new response, one adult who will respond predictably, and one way of recording what happens. The practitioner rehearses the step and agrees what will count as useful information even if the attempt fails. Parents are not given session content; they are given a narrow role: reduce repeated prompting, notice the agreed attempt, and report practical obstacles at a planned review. School receives only the functional adjustment Tobias has approved. At review, the result is mixed. The chosen step works twice and fails once after a night of poor sleep and a peer comment. A weak practitioner might call this inconsistency. The formulation instead becomes more precise: capacity is state-dependent, peer audience changes the task, and adult responses need to be steadier. The next step is redesigned rather than enlarged. This is the clinical discipline the laboratory is intended to teach: evidence from the young person's life revises the plan. By the later sessions, Tobias can describe the pattern without adopting the referral label. Improvement is measured not only by symptom frequency but by participation, recovery time, willingness to seek help, and the adults' ability to respond without escalation. The ending plan names early signs, first responses, trusted people, and the point at which professional help should be sought again. The case remains fictional and simplified, but it demonstrates the movement from explanation to negotiated action.

## Family, school, and cultural translation

Translate the theory into the languages of the systems around the young person. Parents need to know what to do differently on Tuesday evening, not only what the model is called. Teachers need observable adjustments: timing, audience, instruction format, feedback privacy, break arrangements, or response to early signs. Community and health professionals need the specific decision requested from them. A plan that requires everyone to understand the whole theory will fail; a plan that assigns each person one coherent action may succeed. Cultural translation is not achieved by inserting a stereotyped example. Ask how the young person and family explain the difficulty, who is trusted, what privacy means, which adult decisions are collective, what language carries the relevant concepts, and what previous experiences with services shape caution. Check whether the intervention asks the least powerful person to absorb all change. If the school timetable, housing, transport, discriminatory response, or family workload is maintaining distress, consultation and advocacy belong in the treatment plan. Developmental translation requires attention to language, abstract reasoning, attention, memory, autonomy, and dependence. A method designed for adults may need shorter tasks, visual materials, movement, caregiver involvement, school coordination, and more explicit consent. Adaptation is not dilution when the mechanism is preserved and made usable; it is dilution when only the vocabulary is borrowed.

## Common errors and supervision questions

- Using the theory's label as an explanation: “She does that because she is resistant, avoidant, dysregulated, or unmotivated.” Ask what was observed and what else could explain it.
- Selecting an intervention because it is familiar to the practitioner rather than matched to mechanism, evidence, development, and consent.

- Involving family or school so broadly that the young person's confidential space disappears, or excluding them so completely that the environment defeats the work.
- Interpreting lack of progress as client failure before checking fidelity, dose, practical barriers, alliance, risk, and formulation accuracy.
- Moving faster because the service has few sessions, without making the compression explicit or arranging step-down support.
- Recording speculation as fact, especially about motives, trauma history, identity, family intent, or risk.
- What exactly did the young person say they wanted, and how does the plan preserve that aim?
- Which mechanism is the current intervention supposed to change, and what would count as evidence?
- What has been ruled out medically, educationally, culturally, and in safeguarding terms?
- Who else must change a response for the young person's new behaviour to survive?
- What is the practitioner feeling pulled to do—rescue, punish, withdraw, persuade, avoid—and how is that being supervised?
- If only three sessions remained, what should be consolidated rather than newly opened?
- What information does the young person believe is private, and does the record match that understanding?

## Outcome check

Review at least four kinds of outcome. First, **experience**: does the young person feel safer, understood, and more able to choose? Second, **function**: what is happening in learning, attendance, family life, friendship, sleep, and participation? Third, **mechanism**: has avoidance reduced, regulation improved, communication changed, mastery increased, family accommodation shifted, or support become more reliable? Fourth, **system**: are adults and institutions responding differently, and will those changes survive staff absence or term transitions? A symptom score may contribute to each judgement; it cannot replace them. End the laboratory by writing a five-sentence plan: the young person's goal; the formulation in ordinary language; the next intervention and who will carry it; the main ethical or cultural caution; and the date and evidence for review. If those five sentences cannot be written clearly, the theory has not yet become practice.

## Advanced seminar exercises for Assessment Blueprint, Assignments, and Rubrics

**Compare two explanations.** Write two competing explanations of the same adolescent difficulty using **Assessment Blueprint, Assignments, and Rubrics** and one other approach from this book. Each explanation must identify a mechanism, an intervention, a predicted early sign of improvement, and an observation that would weaken the explanation. The exercise prevents theoretical loyalty from replacing reasoning: a model earns its place by the decisions it changes.

**Audit the first three sessions.** Design the first three contacts for a fictional adolescent. State what will be explained, what will not yet be attempted, which adults may be involved, and what record will be created. Pay particular attention to assent, privacy, developmental language, and the difference between the referrer's goal and the young person's goal. Many treatment failures are contracted in the first meeting long before a recognisable technique is used.

**Find the maintaining loop.** Draw a loop with at least five points: context, bodily state or appraisal, protective action, other people's response, and longer-term consequence. Mark where **Assessment Blueprint, Assignments, and Rubrics** would intervene and where a family, school, health, cultural, or practical intervention is more appropriate. Require every arrow to be supported by an observation or labelled as a hypothesis.

**Practise the difficult conversation.** In triads, rehearse explaining the approach to a sceptical adolescent, a worried parent, and a teacher who wants a quick behavioural result. The practitioner must use ordinary language, state limits, invite correction, and avoid promising outcomes. Observers record where jargon, coercion, or false certainty enters. Repeat the conversation after feedback; fluency under challenge is a professional skill.

**Examine power and access.** Ask who defined the problem, who attends, who can refuse, whose record is believed, who pays or travels, whose language is used, and who carries the burden of change. Consider disability, poverty, race, gender, sexuality, care experience, migration, and school status where relevant to the fictional case. Identify one institutional action that should accompany any individual intervention.

**Plan the review.** Choose four outcomes: the young person's experience, daily functioning, the mechanism targeted by **Assessment Blueprint, Assignments, and Rubrics**, and the response of the surrounding system. Specify when each will be reviewed and what decision a disappointing result would trigger—reformulate, adjust dose, involve others, consult, refer, pause, or end. This turns evaluation from a discharge ritual into clinical governance.

**Written consolidation.** In 250 words, explain Assessment Blueprint, Assignments, and Rubrics to a fourteen-year-old, a parent, and a teacher without using the theory's technical label. The three versions should preserve the same core idea while changing vocabulary, examples, and responsibilities. If the explanation only works when the listener accepts the professional's authority, it is not yet clinically usable.

CHAPTER APPENDIX A

# Consent, Assent, and Records Forms

Model documentation for minors, families, and schools.

## A1. Purpose and Use of These Forms

These model forms support counselling with children and adolescents in educational, community, clinic, and private-practice settings. They are teaching templates, not legal advice. Before use, each service must adapt them to current local law, professional regulation, safeguarding policy, record-retention rules, insurance requirements, and organisational governance. Where a young person's safety or legal rights are involved, qualified local advice should be obtained.

Consent is not a signature obtained once and forgotten. It is an ongoing process of explanation, understanding, choice, review, and withdrawal. For minors, legal consent may rest with a parent, guardian, court, or the young person, depending on age, capacity, jurisdiction, and the nature of the service. Assent is the young person's affirmative agreement to participate even where another person provides legal consent. Dissent—refusal, withdrawal, distress, silence, or persistent non-attendance—must be noticed and explored rather than overridden merely because paperwork has been signed.

A form should never promise what the service cannot deliver. Do not promise absolute confidentiality, immediate crisis response outside operating hours, permanent record destruction contrary to retention law, or access to a particular practitioner if staffing cannot guarantee it.

## A2. Core Elements of a Consent Record

A complete counselling consent record should identify:

- the legal name of the young person and the name they wish to be used in sessions and communications;
- date of birth or age range where required for service eligibility;
- parent, guardian, or legal decision-maker details where applicable;
- the service name, practitioner name and role, supervisor or accountable lead where relevant;
- purpose and likely nature of counselling;
- session length, frequency, location or remote platform;
- fees, cancellation rules, and funding source where applicable;
- benefits, alternatives, and foreseeable limitations;
- confidentiality and its limits;
- record creation, access, storage, retention, and sharing;
- communication methods and response times;
- safeguarding and emergency arrangements;
- complaint and advocacy routes;
- the right to ask questions, pause, withdraw, or seek another service;
- signatures, dates, interpreter details, and any adjustments provided.

Where consent is obtained verbally because of literacy, disability, remote access, or urgent circumstances, record who explained the information, what was explained, how understanding was checked, who agreed, and any witnesses or interpreters used under policy.

## A3. Model Information Statement for Parents and Carers

**Service name:** _____

**Practitioner:** _____

**Young person:** _____

Counselling offers a planned space in which a young person can discuss concerns, understand patterns, develop coping and communication skills, and work toward agreed goals. The counsellor may meet the young person alone, meet parents or carers separately, and, where agreed and clinically appropriate, hold joint conversations. The counsellor does not act as a disciplinary officer, custody evaluator, academic tutor, or investigator unless a separate role has been explicitly commissioned and explained.

Sessions normally last _____ minutes and occur _____. The initial plan will be reviewed on or before _____. Progress is evaluated using conversation, agreed goals, functioning at home and school, and, where appropriate, brief questionnaires.

The counsellor will keep records necessary for safe and accountable care. Records are stored by _____ and retained according to _____. Parents and carers may have rights to information under local law and policy, balanced against the young person's confidentiality, safety, and developmental capacity. The counsellor will discuss information-sharing arrangements before counselling begins.

Confidentiality will be maintained except where disclosure is required or permitted to protect the young person or another person from serious harm, to comply with safeguarding procedures or law, or where the young person agrees to sharing. Where possible, the counsellor will discuss proposed sharing with the young person first.

Parents and carers are asked not to require the young person to report session content after appointments. Helpful parental involvement includes supporting attendance, communicating practical concerns, participating in agreed parent sessions, and informing the service promptly about major risks or changes.

In an emergency outside session hours, contact _____. The counselling service does not provide continuous crisis monitoring unless explicitly stated here: _____.

I confirm that the service, its limits, record arrangements, fees or funding conditions, complaint route, and confidentiality limits have been explained in a language and format I could use. I have had an opportunity to ask questions.

Name: _____ Relationship/legal authority: _____

Signature: _____ Date: _____

Interpreter or communication support used, if any: _____

## A4. Young Person's Assent Statement

My counsellor is _____. I understand that counselling is a time to talk, think, practise skills, or use other agreed ways of working on things that matter to me.

I understand that:

- I can say what I think the problem is and what I want to change.

- I can ask what will happen with information I share.
- What I say is private unless the counsellor needs to share information to keep me or someone else safe, or the law/policy says information must be shared.
- The counsellor may need to speak to adults about practical arrangements or safety, but we will discuss what will be said whenever possible.
- I can ask for a pause, say I do not want to answer, or ask for a different way of working.
- I can ask who keeps notes, where they are kept, and how to complain or get support from another adult or advocate.
- If sessions are online or by phone, we will agree where I will be, who can hear, what happens if the connection fails, and how I can contact help in an emergency.
- I can change my mind about counselling. If I stop coming, the counsellor or service may contact me or my parent/carer in the way we agreed, especially if they are worried about safety.

My preferred name in sessions is: _____

Adults may use this name in these settings: _____

Adults should not use this name or share information about counselling in these settings without discussing it with me first: _____

The best safe way to contact me is: _____

I agree to take part in counselling at this time.

Young person's signature or mark: _____ Date: _____

Where a young person does not wish to sign, record assent discussion, questions, preferences, and any dissent or conditions below.

Practitioner record: _____

## A5. Capacity and Communication Checklist

Before relying on consent or assent, consider and record:

- Can the young person understand the purpose and nature of counselling in accessible language?
- Can they retain the main choices long enough to decide?
- Can they weigh obvious benefits, burdens, and alternatives?
- Can they communicate a preference by speech, sign, writing, device, behaviour, or trusted support?
- Are pain, medication, fatigue, intoxication, distress, language, disability, or another person’s presence affecting apparent agreement?
- Has an interpreter, advocate, or communication aid been offered where needed?
- Has the young person had an opportunity to speak without a parent, teacher, partner, or peer present?
- Are there signs of coercion by family, school, partner, peers, or professionals?
- What adjustments were made, and what remains uncertain?

Capacity is decision-specific and may fluctuate. A young person may be able to choose session activities but need support for record-sharing decisions, medical referrals, or complex family meetings.

## A6. Review and Withdrawal Record

Consent and assent should be reviewed when:

- goals or methods materially change;
- a new person joins treatment;
- family or school information-sharing changes;
- teletherapy begins or ends;
- recording, testing, or digital tools are introduced;
- risk or safeguarding status changes;
- the young person reaches a relevant legal age or changes placement;
- treatment extends beyond the period originally explained;
- the young person expresses doubt, dissent, or misunderstanding.

Date of review: _____ People present: _____

What changed: _____

What the young person said: _____

What was agreed: _____

Withdrawal or pause requested by: _____

Safety or continuity actions taken: _____

Referral or information provided: _____

Practitioner signature: _____ Date: _____

## A7. Common Errors to Avoid

Do not use a parent's signature to silence an adolescent's dissent. Do not obtain consent for “counselling” and then introduce trauma processing, group participation, recording, testing, or school reporting without renewed explanation. Do not state that records are confidential if school administrators, insurers, digital platforms, or courts may access them under policy or law. Do not guarantee that a young person can withdraw from safeguarding action. Do not make counselling a condition of avoiding punishment without explaining the mandated frame and preserving meaningful choices inside it.

The ethical test is simple: if the young person, parent, or future reader of the record saw exactly what had been explained and agreed, would they recognise the service that followed?

## A2.1 Confidentiality Agreement for Counselling with Minors

This model should be adapted to law and service policy. It is designed to be read aloud and discussed, not merely signed.

## What stays within counselling

Session conversation, questionnaires, artwork, digital material created for therapy, and the counsellor's process reflections are treated as confidential clinical information. Access is limited to authorised professionals with a legitimate role under policy.

## What may be shared routinely with agreement

Practical information may include attendance, appointment changes, broad progress, agreed goals, safety plans, and recommendations for home or school. The young person should know the wording or substance whenever possible.

Routine sharing agreed:

With parent/carer: _____

With school: _____

With health or social care professionals: _____

Other: _____

## What may or must be shared without agreement

Information may be shared where there is serious risk of harm, suspected abuse or exploitation, a legal duty, a court order, or another lawful safeguarding basis. Only relevant information should be shared, with the minimum necessary audience. Unless doing so would increase danger or obstruct protection, the young person will be told what is being shared, with whom, and why.

## Records

Records may include referral information, consent, assessments, formulations, session summaries, risk and safety plans, correspondence, measures, and endings. They will be stored at _____, retained for _____, and accessed under _____.

The young person and/or parent may request access, correction of factual inaccuracies, or an explanation of record rights through _____. Some third-party or safeguarding information may be limited by law or policy.

## Digital communication

Agreed channels: _____

Response hours: _____

Channels not to be used for clinical or crisis communication: _____

If technology fails during a remote session, the counsellor will: _____

## Signatures and discussion record

Young person: _____ Date: _____

Parent/carer or legal representative, where required: _____

Practitioner: _____ Date: _____

Discussion notes, disagreements, and unresolved questions: _____

## A2.2 Information-Sharing Decision Record

Use one record for each significant non-routine disclosure.

Date and time: _____ Decision-maker: _____

Information proposed for sharing: _____

Source and reliability of information: _____

Purpose of sharing: _____

Legal/policy basis: _____

Young person's views: _____

Parent/carer views, if relevant and safe: _____

Risks of sharing: _____

Risks of not sharing: _____

Minimum information and recipients: _____

Was the young person informed before sharing? Yes / No

If no, why: _____

What was actually shared, by whom, and how: _____

Follow-up required: _____

Supervisor or safeguarding lead consulted: _____

## A2.3 Session Record Template

Client identifier: _____ Date: _____ Session no: ___

Present and setting: _____

Purpose/agenda agreed: _____

Young person's account in their own key words: _____

Observations relevant to care (separate from interpretation): _____

Assessment/formulation update: _____

Interventions used and response: _____

Risk, safeguarding, health, or school issues: _____

Parent/school/professional contact, with consent or lawful basis: _____

Agreements, homework, or practice: _____

Outcome measure or goal rating, if used: _____

Plan and next appointment: _____

Information shared after session: _____

Practitioner signature: _____ Date/time of entry: _____

Records should be written promptly, accurately, respectfully, and without unnecessary intimate detail. Distinguish what was reported, observed, inferred, and decided. Avoid labels such as manipulative, attention-seeking, resistant, or non-compliant without behavioural evidence and context.

## A2.4 Assessment Summary Template

Reason for assessment and decisions it must inform: _____

Sources used and missing sources: _____

Young person's views and goals: _____

Development, health, learning, language, and access needs: _____

Family, peer, school, digital, cultural, and community context: _____

Presenting pattern by setting: _____

Strengths and previous helpful responses: _____

Risk and protective formulation: _____

Standardised measures, scores, limitations, and interpretation: _____

Formulation: _____

Recommendations and responsible persons: _____

Information-sharing plan: _____

Review date and criteria: _____

## A2.5 Referral Letter Template

Dear _____,

I am referring _____ (date of birth/age and preferred name where relevant and consented) for assessment/support with _____.

Reason for referral and decision requested: _____

Relevant background: _____

Current presentation and functioning: _____

Risk and safeguarding information relevant to your role: _____

Strengths, preferences, communication and access needs: _____

Work already undertaken and response: _____

Current professionals and family arrangements: _____

Specific questions for your service: _____

Consent/assent and information-sharing basis: _____

Attachments: _____

Please contact _____ by _____ if further information is required.

Name, role, service, secure contact: _____

## A2.6 Closing Summary Template

Episode dates and number of sessions: _____

Reason for counselling and initial goals: _____

Main formulation in respectful summary form: _____

Interventions and participation: _____

Changes in symptoms, functioning, relationships, participation: _____

Young person's view of progress and remaining concerns: _____

Risk and safety plan at closure: _____

Recommendations for family/school/other services: _____

Referrals made and accepted: _____

How to seek help again: _____

Copies provided to: _____

Practitioner: _____ Date: _____

## A2.7 Record Access and Correction Log

Date request received: _____ Requester and authority: _____

Identity verified by: _____

Records requested: _____

Legal/policy review by: _____

Material released, withheld, or redacted and reasons: _____

Date and method of release: _____

Correction requested: _____

Outcome and notification: _____

Complaints or advocacy information supplied: _____

## A2.8 Retention and Destruction Note

Services must not promise destruction at a date contrary to law, safeguarding requirements, insurance, or organisational retention schedules. When records reach review, record the schedule applied, reviewer, decision, method of secure destruction where authorised, and any legal hold. Digital deletion should include relevant backups and vendor systems as far as contractually and technically possible, with limitations documented.

## A3.1 Teletherapy Consent and Assent Addendum

Counselling may be offered by secure video, telephone, or another approved method. Remote counselling has benefits and limits. Privacy, technology, location, emergency response, and observation may differ from in-person care.

Platform approved by service: _____

Young person's location during sessions: _____

Address or location description to be confirmed at each session: _____

Emergency contact: _____ Local crisis resource: _____

Backup telephone number: _____

If the connection fails, the practitioner will: _____

If the practitioner is concerned about immediate safety, they may contact: _____

People who may be present or nearby: _____

Agreed privacy arrangements and signal if the young person cannot speak freely: _____

Camera expectations and alternatives: _____

Recording, screenshots, automated transcription, and AI tools are not permitted unless separately explained and authorised here: _____

Messaging boundaries and expected response times: _____

Parent/carer role during remote sessions: _____

I understand that I may request in-person or another format where available, and that suitability will be reviewed if privacy, safety, technology, or clinical needs change.

Young person: _____ Date: _____

Parent/carer or legal representative where required: _____

Practitioner: _____ Date: _____

## A3.2 School Counselling Information Statement

School counselling is a supportive service. It is not a disciplinary interview, behaviour sanction, academic assessment, or investigation. The school counsellor may provide brief counselling, consultation to staff, family liaison with appropriate consent, group work, crisis support, and referral.

Students may be referred by staff, family, or themselves. Referral does not mean the student is in trouble. The counsellor will explain who made the referral and why in developmentally appropriate terms.

Session content is confidential within professional and legal limits. Teachers may receive practical recommendations or broad progress information where the student agrees or where policy permits. Teachers will not ordinarily receive transcripts or detailed disclosures. Safeguarding information will be passed to designated staff promptly.

School records created by the counselling service are stored: _____

Staff who can access counselling records: _____

Appointment system and how privacy is protected: _____

Parent/carer notification practice for this age/service: _____

Complaint or advocacy route: _____

The student may ask what information is held, who can see service summaries, and how factual errors can be corrected under policy.

## A3.3 Group Counselling Agreement

Group purpose: _____

Members are expected to attend on time, respect different experiences, avoid recording or screenshots, and not repeat other members' personal disclosures outside the group. The facilitator cannot guarantee that every member will maintain confidentiality; members should share only what they are prepared to have heard in a group.

Members may pass on an activity, ask for a pause, or speak to the facilitator individually. Threats, harassment, sexual or discriminatory comments, and pressure to disclose are not permitted. Safeguarding limits apply.

For online groups, members must join from a private-enough location, use the agreed name display, keep cameras or microphones as agreed, and not invite unapproved people into the session.

Young person's agreement: _____ Date: _____

Parent/carer consent where required: _____ Date: _____

Facilitator: _____ Date: _____

## A3.4 Recording, Observation, and Training Consent

No audio, video, automated transcription, live observation, or use of material for teaching or research should occur without separate, specific consent and assent where required. Consent for treatment does not imply consent for recording or publication.

Purpose of recording/observation: _____

Who will access it: _____

Where and how long it will be stored: _____

Whether excerpts may be used in supervision, training, assessment, or research: _____

Whether the young person/family may stop recording: _____

Date after which consent expires: _____

I understand that declining recording or observation will not reduce access to ordinary care, except where a specific training clinic model has been explained before acceptance into that service.

Signatures: _____

Withdrawals and destruction actions should be logged. Even anonymised case material can be identifiable; teaching use requires disguise, minimisation, and institutional approval.

## A3.5 Consent for Standardised Testing or Digital Tools

Instrument/tool name: _____

Purpose and decision it will inform: _____

What the young person will do and how long it will take: _____

Alternatives: _____

Limitations, language and cultural considerations: _____

Who will see raw data, scores, reports, and vendor-processed data: ____

Data location, retention, deletion, and secondary use: _____

Feedback arrangements: _____

Consent/assent signatures and date: _____

A score must be interpreted by a competent practitioner in context. Automated recommendations, including AI-generated outputs, require human review and must not be the sole basis for diagnosis, safeguarding, school placement, or treatment decisions.

## A3.6 Consent Where Parents Are Separated or Legal Authority Is Disputed

Record, from reliable documentation where available:

- persons with parental responsibility or legal authority;
- court orders affecting contact, health, education, residence, travel, or information;
- who may consent to counselling and receive information;
- safeguarding restrictions on addresses, schools, photographs, or contact;
- who should receive appointment messages;
- any disagreement and legal advice or court direction obtained.

Do not rely solely on one adult's account where documents are available and conflict is known. Do not disclose a protected address or school. Where parents disagree about non-urgent counselling, follow local law and policy, consider the young person's views and best interests, and obtain legal or senior advice where necessary.

The young person should not be used as messenger between adults. Session arrangements should avoid placing them in loyalty conflicts.

## A3.7 Mandated Counselling Statement

You have been referred by _____. Attendance or participation may be required by _____. The counsellor will explain what attendance information, if any, must be reported, to whom, and in what words.

Within that requirement, you may still make choices about goals, pace, topics, and methods where clinically and legally possible. The counsellor will not pretend that mandated attendance is fully voluntary. Concerns

about the mandate can be raised through _____.

The counsellor's clinical opinions and reports, if any, are limited to: ____

Young person's acknowledgement of explanation: _____

This statement is especially important in school discipline, court, child protection, and employer- or insurer-funded contexts.

## A3.8 Periodic Consent Review Prompts

At review, ask:

- Do you still understand why counselling is happening?
- What has been helpful, unhelpful, surprising, or uncomfortable?
- Is there anything you believed would stay private that has been shared?
- Has who you want involved changed?
- Has the safest contact method, name, pronoun, address, school, or platform changed?
- Do you want to continue, pause, change method, involve someone new, or end?
- Are there records or summaries you want explained or corrected?
- What should happen if you stop attending?

Document the answers in the young person's words where material. Consent is alive only if review can alter practice.

CHAPTER APPENDIX B

# Case Study Portfolio

Twelve extended composite case studies for seminar use.

## B1. How to Use This Portfolio

The cases in this appendix are fictional composites created for teaching. Any resemblance to an identifiable person is unintended. They are designed to help students integrate theory, development, culture, ethics, and planning. Names, settings, and details should not be copied into real records.

For each case, students should produce:

1. a concise presenting summary;
2. a five-part formulation;
3. at least two competing theoretical readings;
4. a risk and safeguarding analysis;
5. a sequenced treatment plan;
6. family, school, and service coordination;
7. outcome measures and review points;
8. a young-person-friendly explanation of the plan;
9. an account of what the practitioner might be getting wrong.

The portfolio is not a test of finding one hidden diagnosis. Strong work tolerates uncertainty, identifies missing information, and states what observation would change the formulation.

## Case 1: The Boy Who Arrived After the Bell

**Age and context.** Tunde, thirteen, lives with his mother and younger sister. His father works abroad for long periods. Tunde was a regular attender in primary school. Since moving to secondary school he arrives late three or four days a week, misses registration, and has received repeated detentions. Teachers describe him as bright, funny, and increasingly rude when challenged publicly.

**History.** Tunde changes buses once. The second bus is unreliable. At home, his mother leaves for work before he wakes. His nine-year-old sister depends on him to check that the door is locked and that she has her school bag. Tunde stays up late playing online games with cousins in another time zone. He says mornings feel “impossible” and that detention is “better than walking in when everyone looks”.

**Observations.** He concentrates well in afternoon lessons. He is popular but avoids reading aloud. Screening suggests possible dyslexic difficulties not yet assessed. His mother feels blamed by school letters. She says Tunde “chooses games over his future”. Tunde says adults only contact home when he is in trouble.

**Student tasks.** Separate lateness as behaviour from explanations. Analyse sleep, transport, caring responsibility, public shame, literacy, family communication, and school sanctions. Design a plan that does not make Tunde responsible for adult transport failures. Identify what should change at home, in school systems, and in Tunde's routines. State what information is missing about his father's role, the sister's school arrangements, and the journey.

**Teaching point.** A behaviour can be simultaneously a skill problem, a systems problem, a developmental problem, and a rational response to humiliation. Contingency management without ecological change would be efficient-looking and unjust.

## Case 2: The Girl Who Became the Family Interpreter

**Age and context.** Mei, fifteen, migrated with her parents and grandmother two years ago. She is fluent in the school language and interprets for medical appointments, housing letters, and parent evenings. Teachers praise her maturity. She has developed stomach pain, declining grades, and anger at home.

**History.** Her mother has chronic illness; her father works nights. Mei's grandmother tells stories about the family's former home and worries that Mei is "losing respect". Mei has stopped attending an art club because appointments and homework translation take priority. She says, "If I don't do it, nobody understands anything. If I do it, I get told things a child shouldn't know."

**Risk and needs.** No suicidal thinking is reported. She has missed meals before examinations and says pain improves at weekends. Medical assessment has not yet occurred. Her parents value education highly and feel ashamed that services know about family difficulties.

**Student tasks.** Formulate parentification, migration loss, language brokering, gender expectations, somatic symptoms, and school pressure. Identify professional interpreter needs and medical steps. Design family work that redistributes adult responsibilities without shaming parents. Consider how to ask Mei what she wants adults not to know through her interpreting role.

**Teaching point.** Competence can conceal burden. A strengths-based reading that only celebrates maturity will collude with the system extracting resilience from her.

## Case 3: Two Homes, Two Rules, One Phone

**Age and context.** Leo, fourteen, lives alternately with separated parents. His mother permits phone use until 10 p.m.; his father removes all devices on arrival. Leo has begun keeping a second phone given by an older cousin. School reports conflict after weekends at his father's home.

**History.** The separation followed high conflict. Each parent asks Leo what happens at the other home. Leo tells each what reduces immediate questioning. His grades are stable, but he has stomach aches on transition days and has started refusing to go to his father's home, then crying afterward because he misses him.

**Student tasks.** Map loyalty binds, transitions, surveillance, autonomy, peer contact, and inconsistent contingencies. Distinguish safety monitoring from interrogation. Draft a parent-only meeting agenda that does not use Leo as messenger. Identify what information the counsellor should and should not carry between households.

**Teaching point.** Consistency does not require identical households. Children can manage different rules when transitions are predictable, adults communicate directly, and differences are not framed as proof that one home is corrupt.

## Case 4: The Student Who Was "Fine" All Day

**Age and context.** Amelie, twelve, is quiet, compliant, and academically successful. At home she cries for long periods, refuses food on some evenings, and repeatedly asks whether her parents are angry. Teachers are surprised by the referral.

**History.** Her parents separated amicably but both work long hours. Amelie cares for a younger brother after school. She worries about saying the wrong thing and checks doors and messages repeatedly. She says

school is easier because “the rules are on the wall; at home I have to guess”.

**Student tasks.** Explore masking, anxiety, reassurance, perfectionism, caring responsibilities, family emotional communication, eating and medical assessment, and the risk of schools dismissing distress because attainment is high. Plan parent work and graded reduction of reassurance without abrupt withdrawal of comfort.

**Teaching point.** Functioning is setting-specific. High achievement can coexist with severe distress and may delay recognition.

## Case 5: The Assembly

**Presentation.** Sena, thirteen, vomited before a school assembly after being asked to read. She now avoids corridors, group work, presentations, and the dining hall. She can speak comfortably with two friends and at home.

**Data.** Her attendance is 62 per cent. She fears vomiting and being watched swallowing. Parents initially allowed her to remain home on presentation days. A teacher once commented, “We haven't got all day,” when she paused. She has no eating disorder symptoms reported, but medical causes for nausea have not been assessed.

**Tasks.** Conduct differential assessment among social anxiety, panic, specific phobia, trauma response, medical problems, and school-based humiliation. Build a hierarchy that starts with success and includes checking feared outcomes. Analyse parental accommodation and teacher practices. Identify measures beyond attendance.

**Expected integration.** CBT/exposure principles, social cognitive mastery, IPT-A peer issues, school consultation, family work, and developmental sensitivity to shame.

## Case 6: The Empty Calendar

**Presentation.** Jonas, sixteen, stopped attending college after failing two assessments. He sleeps until afternoon, games at night, and says he is “not depressed, just done”. His mother finds unopened letters from college. He has lost contact with friends.

**Data.** He previously wanted to study engineering. He describes every task as evidence that he is behind. He avoids messages because they contain deadlines. He denies suicidal intent but says the future feels “blank”. Appetite and concentration are poor.

**Tasks.** Assess depression, suicide risk, substance use, sleep, learning problems, physical health, and family responses. Construct a behavioural activation plan with mastery and social contact. Use motivational interviewing to explore the apprenticeship/college discrepancy. Identify how academic backlog should be triaged so return does not recreate failure.

**Teaching point.** Avoidance may protect against shame in the short term while removing every source of reward and competence.

## Case 7: The Perfect Score

**Presentation.** Hana, fifteen, studies five hours nightly, cries over minor errors, checks homework repeatedly, and refuses to submit work she considers imperfect. Teachers describe her as a model student. She has headaches and insomnia.

**History.** Her older sibling received a prestigious scholarship. Hana says her parents never pressure her, but family conversation often centres on rankings. She fears disappointing teachers and being exposed as "actually average".

**Tasks.** Formulate perfectionism across cognitive, family, cultural, school, and identity dimensions. Distinguish excellence from compulsive checking. Design experiments in "good-enough" submission, sleep protection, and family feedback changes. Consider obsessive-compulsive assessment.

**Teaching point.** A school may reinforce the very pattern that harms the student because it produces desirable outputs.

## Case 8: The Friend Who Did Not Reply

**Presentation.** Bea, fifteen, has self-harmed twice after friendship conflicts and sends repeated messages seeking reassurance. She describes friends as either perfect or cruel. Adults use the phrase "attention-seeking".

**Safety note.** This fictional case requires a full current risk assessment in any teaching discussion. Do not treat the vignette as sufficient information for real intervention.

**Tasks.** Apply IPT-A, mentalization, emotion-focused, attachment, and DBT-informed lenses. Identify where each lens helps or risks blame. Develop a crisis plan, family communication plan, and school response that avoids both punitive withdrawal and unlimited reassurance. Examine staff language and team splitting.

**Teaching point.** Behaviour described as attention-seeking is often attachment- and safety-seeking expressed under high arousal. The task is to make safer bids more effective, not to make need disappear.

## Case 9: The Quiet Ward of One

**Presentation.** Kofi, eleven, recently placed in foster care, is polite with adults and refuses school. He hoards food in his room, wets the bed, and becomes distressed when routines change. He has had three schools in two years.

**Tasks.** Use trauma-informed, attachment, developmental, ecological, and educational perspectives. Prioritise placement stability, predictable routines, school transition, medical and continence assessment without shame, and carer support. Decide what trauma-specific work, if any, is appropriate now.

**Teaching point.** Stabilisation is treatment, not waiting. A new therapy relationship cannot compensate for repeated environmental discontinuity unless the system also changes.

## Case 10: The Joke That Travelled

**Presentation.** A private joke image of Priya, fourteen, is altered and shared beyond the intended group. She refuses school, deletes accounts, then creates new anonymous accounts at night. Some students claim she "sent it first" and should expect consequences.

**Tasks.** Address safeguarding, online exploitation or bullying pathways, school response, family support, sleep, peer bystanders, and the distinction between consensual sharing and non-consensual redistribution. Avoid victim blaming. Plan graded school return and digital safety without demanding that Priya educate the school.

**Teaching point.** Digital harm is interpersonal, institutional, and embodied. Individual coping cannot substitute for platform, peer, and school action.

## Case 11: The Eldest Daughter's Timetable

Ruth, seventeen, organises medication, translates appointments, cooks for siblings, and supports her mother after night shifts. School calls her exceptional. She has stopped applying for courses away from home and says she has no preferences “as long as everyone is okay”.

Students should examine young caring, gendered expectations, family resources, cultural values, identity foreclosure, and service responsibility. A successful plan reduces extracted resilience rather than praising it. Include respite, young-carer assessment, adult interpreting, school flexibility, and supported exploration of futures. Ask what Ruth might want if wanting did not feel disloyal.

## Case 12: The Name on the Register

Alex, fifteen, uses a chosen name with friends and a different name at home. A school system automatically prints the legal name on a classroom list projected to the class. Alex leaves school and refuses to return until “adults stop making it a thing”.

Students should address administrative safety, confidentiality, bullying, family disclosure planning, staff training, record systems, and the difference between affirmation and forced visibility. The first intervention may be technical: change the list. Identity support fails when databases keep outing the student.

## Case 13: The House with Two Alarms

Fatima, thirteen, lives with her mother and stepfather. She becomes aggressive after school but is calm in lessons. Her mother says Fatima saves all anger for home. Teachers suspect the school report is exaggerated.

Students should avoid assuming home is either safe or unsafe based on one setting. Explore after-school restraint collapse, sensory load, sleep, family conflict, possible neurodevelopmental needs, and the mother's experience. Design observation across settings and a decompression routine. Assess safeguarding directly and separately.

## Case 14: The Boy Who Coached Himself

Diego, twelve, is an talented footballer who panics before matches. He watches elite athletes online and compares his body and performance. His coach praises “mental toughness” and benches players who show distress.

Students should integrate anxiety, body image, social learning, sport culture, parent and coach behaviour, and performance systems. Intervention may include graded exposure, coping models, coach consultation, sleep and nutrition referral, and redefining courage as flexible participation rather than suppression.

## Case 15: A New Country, an Old Profession

Samira's mother was a pharmacist before migration and now cleans at night. Samira interprets for her and feels both proud and trapped. Her mother grieves status loss but tells school she is “fine”.

Students should explore intergenerational acculturation, credential recognition, grief, language brokering, class change, racism, and family pride. The counsellor should not turn structural loss into a communication exercise alone. Community, employment, language, and credential-navigation resources are part of care.

## Case 16: The Student Council President

Nia, seventeen, leads campaigns, supports friends, and achieves top grades. She presents after fainting and admitting she eats very little before school events. She says asking for help would make her “a fraud”.

Students should arrange medical assessment, explore perfectionism, identity, social reward for selflessness, family and school expectations, and possible eating disorder pathways. The plan must not rely solely on insight. High public functioning can conceal high private risk.

## Integrative Questions for Cases 11–16

1. Which adult system benefits from the young person's current coping?
2. Which strength is being overused until it becomes a burden?
3. What would change if the institution altered one routine?
4. What identity story is available to the young person besides patient, carer, problem, or high achiever?
5. Which professional is coordinating, and does the young person know?
6. What cultural assumptions did your first formulation make?
7. What outcome would the young person call success?
8. What would make you stop, refer, or escalate?

## Case 17: The Revolving Door

**Presentation.** Mara, sixteen, has had four counsellors in eighteen months due to staff turnover, placement change, and service age thresholds. She attends once, tells a detailed trauma history quickly, then does not return. Records describe “poor engagement”.

**Formulation prompts.** Consider attachment, epistemic trust, service discontinuity, assessment fatigue, and the possibility that rapid disclosure is a test or a learned attempt to secure help before disappearance. The system may be training the pattern it condemns.

**Plan prompts.** Offer continuity guarantees that are actually deliverable, a named backup practitioner, a concise shared formulation so Mara does not restart from zero, control over pacing, and an explicit repair

route after missed sessions. Measure trust and participation, not only symptoms.

## Case 18: The Examination Countdown

**Presentation.** Eli, seventeen, studies at a high-performing school. He has panic attacks, insomnia, and thoughts that failure would "prove" he has wasted his parents' sacrifices. His parents immigrated and work long hours. They say they never pressure him.

**Formulation prompts.** Examine explicit and implicit expectations, perfectionism, family sacrifice narratives, school comparison systems, sleep, caffeine, identity, and possible depression or obsessive-compulsive symptoms. Avoid reducing parental love to pressure or Eli's ambition to pathology.

**Plan prompts.** Medical and risk assessment; sleep protection; examination planning; graded exposure to imperfect work; family conversation about love, worth, and disappointment; school advocacy on mock examination feedback; career exploration that widens the definition of a viable future.

## Case 19: The Sibling Who Became Security

**Presentation.** Owen, ten, follows his seven-year-old autistic brother everywhere at school and intervenes in peer conflict. Staff praise him. Owen has stomach pain and refuses clubs because "he might need me".

**Formulation prompts.** Sibling subsystem, parentification, school reliance on a child for supervision, anxiety, disability support gaps, and family stress.

**Plan prompts.** Increase adult supervision and sibling support; give Owen protected peer time; create a plan for his brother that does not depend on Owen; family session validating both children's needs. Do not solve an institutional staffing issue through a child's vigilance.

## Case 20: The Last Ten Minutes

**Presentation.** In nearly every counselling session, Hana, fifteen, becomes distressed in the final ten minutes and asks to stay longer. The counsellor repeatedly overruns, then feels resentful. Hana says sessions are the only place adults do not rush her.

**Formulation prompts.** Attachment, endings, time boundaries, possible testing, session pacing, unprocessed material introduced too late, and practitioner countertransference.

**Plan prompts.** Structure sessions with a closing phase, summarise earlier, agree what can be carried safely, plan post-session support, and address the pattern collaboratively. Reliability includes ending on time with warmth, not only extending in crisis.

## Model Integrative Plan Skeleton

**Young person's stated goal:** _____

**Safety and consent position:** _____

**One-paragraph formulation:** _____

**First stabilising changes (system and individual):** _____

**Primary therapeutic focus and theory:** _____

**Family/school/service actions:** _____

**Skills or mastery sequence:** _____

**What will not be attempted yet, and why:** _____

**Measures and youth-defined outcomes:** _____

**Review date and decision rules:** _____

**Relapse/ending/transfer plan:** _____

## Portfolio Marking Guidance

High-quality portfolio work:

- distinguishes facts, reports, inferences, and unknowns;
- centres the young person's voice without treating it as the only evidence;
- integrates development, culture, family, school, and material context;
- names risk and protective processes dynamically;
- sequences interventions rather than collecting techniques;
- assigns institutional responsibilities to institutions;
- protects confidentiality and obtains meaningful assent;
- identifies practitioner limits and referral points;
- states outcomes that matter in ordinary life;
- revises formulation when evidence changes.

Weak work diagnoses from a paragraph, stereotypes culture, blames parents or the young person, lists brand-name therapies, ignores safeguarding, or proposes individual coping for structural harm.

## Additional Short Cases for Timed Formulation Practice

Use one case in a thirty-minute exercise: five minutes to identify facts and unknowns, ten minutes for a five-part formulation, five minutes for competing theory readings, five minutes for a sequenced plan, and five minutes for ethical and outcome review.

### Case 21: The Unopened Envelope

A seventeen-year-old avoids opening college messages after one rejection and says the future has “already decided”. Focus areas include depression, avoidance, shame, family expectations, academic triage. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 22: The Seat by the Door

A twelve-year-old insists on sitting near exits and becomes distressed when classroom seating changes. Focus areas include anxiety, safety behaviour, sensory context, teacher consultation. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 23: The Captain Who Quit

A talented team captain leaves sport after panic symptoms and online criticism of a missed goal. Focus areas include performance anxiety, social learning, body image, coaching culture. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 24: The Brother on Guard

A ten-year-old monitors his disabled sibling at school and refuses clubs. Focus areas include sibling subsystem, parentification, school support gaps. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 25: The Group Chat Election

A student is removed from a friendship group chat and begins checking messages through another pupil’s account. Focus areas include belonging, digital surveillance, peer dispute, school safety. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 26: The Quiet High Achiever

A student with excellent grades cries nightly, checks work repeatedly, and cannot submit “imperfect” assignments. Focus areas include perfectionism, OCD assessment, family and school reinforcement. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 27: The New Pronunciation

A migrant student stops speaking in class after classmates imitate her accent. Focus areas include language, racism, shame, interpreter and school action. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 28: The Sunday Bag

A child packs a bag repeatedly before contact visits and becomes ill on transition mornings. Focus areas include separated families, transitions, loyalty, predictable planning. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 29: The Student Who Sleeps in Class

A fifteen-year-old falls asleep in morning lessons after caring for a parent at night. Focus areas include young caring, sleep, poverty, school flexibility. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 30: The Locker Room Detour

A student takes a long route to avoid changing rooms and is sanctioned for lateness. Focus areas include bullying, body privacy, facilities, safeguarding. Students should identify what must be assessed before

intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 31: The Apology Tour

After every argument, a young person sends long apologies to friends and panics until each replies. Focus areas include reassurance, shame, mentalizing, peer communication. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 32: The Empty Chair at Dinner

A bereaved adolescent leaves the table when a grandparent's former seat is discussed. Focus areas include grief, family rituals, school support, meaning. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 33: The Second Phone

A teenager keeps a hidden phone after inconsistent device rules across two homes. Focus areas include autonomy, transitions, parental conflict, digital safety. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 34: The Girl Who Translated Everything

A fifteen-year-old interprets medical letters and misses her own activities. Focus areas include language brokering, parentification, professional interpreters. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond

symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 35: The Boy Who Laughed First

A student jokes whenever corrected and is described as having no respect. Focus areas include shame, peer audience, discipline, restorative approaches. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 36: The Missing Lunch

A student avoids the dining hall because queues are noisy and seating is socially unpredictable. Focus areas include sensory load, anxiety, school design, graded participation. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 37: The Last-Minute Genius

A student produces strong work only under extreme deadline pressure and sleeps poorly. Focus areas include procrastination, perfectionism, reward timing, study systems. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 38: The Helper Who Never Asked

A student supports every friend in crisis but conceals her own self-harm urges. Focus areas include identity, help seeking, peer burden, risk assessment. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist

diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 39: The Protest at the Gate

A student refuses to enter school after a search policy they experience as discriminatory. Focus areas include institutional trust, rights, discrimination, consultation. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

## Case 40: The Bedroom Studio

An adolescent spends nights making music online, gains supportive collaborators, and falls asleep at school. Focus areas include digital creativity, belonging, sleep, family negotiation. Students should identify what must be assessed before intervention, which adult or institutional response may be maintaining the difficulty, what the young person identifies as a good outcome, and what first step is small enough to test. Include one outcome beyond symptom reduction—participation, recovery time, relationship quality, sleep, belonging, or help seeking—and state what information would lead you to refer or escalate. The strongest responses will resist diagnosing from the vignette and will show how culture, development, family, school, and material context alter the plan.

CHAPTER APPENDIX C

# Theory Comparison Matrices

Side-by-side comparison of all theories covered in the course.

## C1. How to Use These Matrices

These matrices are revision and supervision tools, not league tables. A theory should be judged against a specific young person, problem, context, goal, evidence base, practitioner competence, and risk profile. “Best” in one row may be irrelevant or unsafe in another.

## Matrix 1: Foundational Orientation

| Theory/family | Person viewed as | Main source of difficulty | Primary change process | Counsellor role |
|---|---|---|---|---|
| Person-centred | Self-directing person under conditions of worth | Incongruence and denied experience | Empathy, congruence, unconditional positive regard | Facilitative witness |
| Existential | Freedom-bearing person facing finitude and choice | Avoidance of meaning, freedom, isolation, mortality | Authentic encounter and responsibility | Philosophical companion |
| Gestalt | Organism in contact with environment | Interrupted awareness and contact | Present-focused awareness and experiment | Active facilitator |
| Cognitive therapy | Information processor shaped by schemas | Maladaptive appraisal and belief | Testing and restructuring cognition and behaviour | Collaborative empiricist |
| REBT | Thinking and evaluating agent | Rigid demanding beliefs | Disputation and new philosophy | Direct teacher-coach |
| Behaviour therapy | Learner in environments | Conditioning, reinforcement, avoidance, skill deficits | New learning and contingency change | Designer and coach |
| Family systems | Person in relational systems | Interaction patterns, structure, boundaries, sequences | System reorganisation | System consultant |
| Attachment-based | Relational being shaped by care | Insecure expectations and regulation difficulties | Responsive relationships and repair | Secure-base figure/coach |
| Narrative | Author within discourses | Problem-saturated stories and power | Externalisation and re-authoring | Co-editor and witness |
| Solution-focused | Resourceful actor | Problem talk and overlooked exceptions | Exceptions, goals, small steps | Curious questioner |
| Trauma-informed | Adaptive survivor in context | Threat responses and unsafe conditions | Safety, stabilisation, paced processing | Safety partner and coordinator |
| Mentalization-based | Mind interpreting minds | Mentalizing collapse under arousal | Curiosity, affect reflection, epistemic trust | Not-knowing co-thinker |

## Matrix 2: Adolescent Suitability and Cautions

| Approach | Often useful when | Adapt for adolescents by | Use caution when |
|---|---|---|---|
| Person-centred | Shame, low agency, need for trust | Add structure, family/school context, active safeguarding | Risk requires directive coordination |
| Existential | Identity, grief, choice, meaning | Use concrete language and developmental framing | Acute crisis or severe concrete thinking dominates |
| Gestalt | Avoided emotion, contact interruption | Short experiments, choice, play/media | Flooding, dissociation, body shame |
| CBT | Anxiety, depression, panic, specific beliefs | Examples, family/school practice, shorter tasks | Literacy, neurodivergence, unsafe environments not adapted |
| REBT | Rigid self-demands and frustration intolerance | Humour carefully, collaborative language | It sounds blaming or argumentative |
| Behavioural | Observable avoidance, skills, routines | Youth-chosen reinforcers, adults change contingencies | Behaviour is communication of danger or unmet need |
| Family systems | Conflict and maintaining sequences | Protect youth voice and individual space | Abuse or coercive control makes joint work unsafe |
| Attachment | Relational insecurity and carer capacity | Work through caregivers and trusted adults | Placement instability overwhelms dyadic work |
| Narrative | Shame and imposed labels | Drawings, letters, groups, school documents | Material danger is story-treated instead of changed |
| Solution-focused | Engagement and practical goals | Concrete scales and youth language | Pain is bypassed or risk minimised |
| EMDR/trauma-focused | Discrete processed trauma memories | Preparation, caregiver, short sets, stabilisation | Ongoing threat, instability, untrained delivery |
| MBT | Self-harm, relational crises, affect instability | Family/team mentalizing and crisis plans | High arousal, unsafe family interaction, jargon |
| IPT-A | Depression linked to grief/disputes/transitions | Family and school involvement, social media context | Severe risk or non-interpersonal mechanisms dominate |
| MI | Ambivalence and mandated contact | Autonomy transparency and youth values | Used manipulatively to manufacture consent |

## Matrix 3: Presenting Pattern to First Questions

| Presentation | Ask first | Possible mechanisms | Do not miss |
|---|---|---|---|
| School refusal | Which lessons, routes, people, times? What happens after staying home? | Avoidance, bullying, panic, learning gap, family accommodation, sleep, transport | Safeguarding, medical issues, SEND/access, unsafe school conditions |

| Presentation | Ask first | Possible mechanisms | Do not miss |
|---|---|---|---|
| Aggression | What precedes escalation? What does it stop or obtain? | Escape, status, pain, impulsivity, trauma state, communication limits | Weapon risk, abuse, neurodevelopment, mood disorder, adult escalation |
| Self-harm | Current intent, plans, means, functions, supports | Affect regulation, shame, interpersonal crisis, trauma, depression | Medical care, coercion, online harm, access to means |
| Low mood | Sleep, activity, reward, relationships, loss, future | Withdrawal, anhedonia, grief, conflict, illness, isolation | Suicide risk, bipolar features, substances, eating, thyroid/medical review |
| Aggression at home only | What happens after school? Who sees what? | Restraint collapse, family sequence, sensory load, safety cues | Domestic abuse, carer exhaustion, sibling risk |
| Silence/non-speaking | Where, with whom, since when, what helps? | Anxiety, language, trauma state, communication difference, protest | Selective mutism assessment, hearing/language, coercion |
| Eating restriction | Medical status, history, body image, control, family meals | Anxiety, sensory issues, eating disorder, GI illness, trauma | Urgent medical risk, growth, electrolytes per medical advice |
| Substance use | Function, pattern, peers, supply, consequences | Coping, belonging, dependence, trauma, exploitation | Withdrawal, county-lines/exploitation, polysubstance risk |
| Perfectionism | What error means, checking, sleep, feedback | Shame, cognitive rigidity, family/school contingencies, OCD | Eating, self-harm, obsessive-compulsive disorder, burnout |
| Friendship crisis | Sequence, interpretations, digital context, support network | Mentalizing collapse, dispute, exclusion, identity, bullying | Image sharing, coercion, suicidal response |

## Matrix 4: Mechanism-to-Intervention Guide

| If the main mechanism is… | Consider… | Pair with… |
|---|---|---|
| Avoidance negatively reinforced | Graded exposure and response prevention | Family accommodation reduction, school plan |
| Low reward and withdrawal | Behavioural activation | Sleep, social connection, academic triage |
| Low mastery/self-efficacy | Graded tasks, coping models, feedback | Social cognitive planning |
| Skill deficit | Instruction, modelling, rehearsal, homework | Generalisation in real settings |
| Escalating family sequence | Parent coaching, communication analysis | School alignment, safety plan |

| If the main mechanism is… | Consider… | Pair with… |
|---|---|---|
| Shame-based identity story | Narrative externalisation | Affirmative support and system change |
| Mentalizing collapse | Stop–rewind–explore, affect naming | Crisis plan and team consistency |
| High autonomic arousal | Grounding, orienting, movement, sleep | Trauma phase assessment |
| Interpersonal dispute | IPT-A communication and decision analysis | Family/school negotiation |
| Ambivalence | Motivational interviewing | Practical barrier removal |
| Grief | Grief support, IPT-A, narrative and family rituals chosen by family | School flexibility and memorial boundaries |
| Structural harm | Advocacy, consultation, safeguarding, service coordination | Individual coping only as adjunct |

## Matrix 5: Evidence and Implementation Questions

For every intervention selected, answer:

1. For which age group and problem was it tested?
2. Were young people like this one excluded?
3. What training and supervision are required?
4. How many sessions and what setting?
5. What adverse effects or burdens exist?
6. What outcome will be measured, by whom, and when?
7. What family, cultural, linguistic, disability, or digital adaptations are needed?
8. What would make us stop or refer?

A model is not implemented merely because its name appears in a plan. Fidelity, dose, sequencing, and context are part of evidence-based practice.

## Matrix 6: Session Focus Selector

| If the young person arrives… | First priority may be… |
|---|---|
| In immediate danger | Safeguarding, medical or crisis action |
| Highly aroused | Regulation, safety, reduced demand |
| Blank or dissociated | Orientation, choice, gentle pacing |
| With an urgent practical problem | Problem-solving and advocacy |
| Ready to review homework/exposure | Specific feedback and mastery attribution |
| After a family rupture | Repair, sequence analysis, safety |

| If the young person arrives… | First priority may be… |
|---|---|
| Before a known transition | Rehearsal, supports, contingency planning |
| At planned ending | Consolidation, relapse plan, transfer of supports |

CHAPTER APPENDIX D

# Glossary of Terms

A comprehensive glossary of theory, practice, and developmental terminology.

This glossary prioritises working definitions for students. It does not replace diagnostic manuals, statutes, or specialist texts.

## Key Terms at a Glance

- **Abstinence violation effect** — A lapse after a period of abstinence interpreted as total failure, increasing risk of full relapse.
- **Accommodation (family)** — Family changes that reduce a young person's immediate distress but may maintain avoidance or symptoms.
- **Acting out** — Expressing conflict or feeling through action rather than words or reflection.
- **Active listening** — Listening that communicates attention through posture, minimal encouragers, reflection, and summary.
- **Activity scheduling** — Planning valued, mastery, social, and restorative activities as part of treatment.
- **Acute risk** — Immediate or near-term danger requiring urgent action.
- **Adaptive behaviour** — Behaviour that helps a person manage demands in a context, even if it has longer-term costs.
- **Adolescence** — Developmental period involving puberty, identity, autonomy, peer belonging, and transition toward adult roles; boundaries vary.
- **Adverse childhood experiences (ACEs)** — Potentially traumatic events or conditions in childhood associated at population level with later health risks.
- **Affect** — Observable expression of emotion.
- **Affect regulation** — Processes by which emotional arousal is noticed, tolerated, modulated, and expressed.
- **Affirmation** — In motivational interviewing, specific recognition of strengths, values, effort, or autonomy.
- **Agency** — Capacity to initiate action and influence one's life within real constraints.
- **Agenda mapping** — Collaboratively identifying and prioritising topics for change.
- **Agoraphobia** — Anxiety and avoidance concerning places or situations from which escape may be difficult or help unavailable during panic-like symptoms.
- **Alliance** — Collaborative therapeutic relationship involving bond, goals, and tasks.
- **Ambivalence** — Simultaneous reasons for and against a change or course of action.
- **Amplification** — Gestalt or reflective technique of exploring an experience more fully; must be used without flooding.
- **Anhedonia** — Reduced ability to experience pleasure or interest.
- **Antecedent** — Event or condition occurring before a behaviour in functional analysis.

## Key Terms at a Glance (continued)

- **Anxiety** — Anticipatory fear response involving cognition, physiology, and avoidance or preparation.
- **Applied behaviour analysis (ABA)** — Systematic application of learning principles to socially significant behaviour, including functional assessment.
- **Approach behaviour** — Movement toward a feared, valued, or needed stimulus or goal.
- **Arousal** — Physiological and psychological activation.
- **Assertiveness** — Communicating needs and boundaries while respecting others.
- **Assessment** — Systematic gathering and interpretation of information for decisions.
- **Assent** — A young person's affirmative agreement to participate, distinct from legal consent.
- **Assimilation (cognitive)** — Interpreting new experience through existing schemas; in cultural contexts it may have different meanings and should be defined locally.
- **Attachment** — Enduring relational system involving proximity, safe haven, secure base, and expectations of care.
- **Attachment figure** — Person used for comfort, protection, and exploration support.
- **Attending** — Practitioner behaviours that communicate presence and attention.
- **Attention-maintained behaviour** — Behaviour maintained partly by social responses it produces.
- **Attribution** — Explanation assigned to an event or behaviour.
- **Automatic thought** — Rapid evaluative thought arising in a situation.
- **Autonomic nervous system** — Nervous system divisions involved in arousal, digestion, cardiovascular and threat responses.
- **Autonomy** — Self-direction consistent with development and safety.
- **Avoidance** — Behaviour that prevents contact with feared, painful, or demanding stimuli and is often negatively reinforced.
- **Baseline** — Measurement before intervention used for comparison.
- **Behaviour** — Observable action; some traditions also include private events defined functionally.
- **Behavioural activation** — Treatment increasing rewarding, mastery, social, and value-based activity to interrupt depressive withdrawal.
- **Behavioural experiment** — Planned test of a belief or prediction through action.
- **Belonging** — Experience of acceptance, recognition, and participation in a group or setting.
- **Bibliotherapy** — Guided use of reading materials as an adjunct to care.
- **Bilateral stimulation** — Alternating sensory stimulation used in EMDR protocols.

## Key Terms at a Glance (continued)

- **Biopsychosocial model** — Framework considering biological, psychological, and social factors together.
- **Body scan** — Attention moved systematically through bodily sensations; requires consent and trauma sensitivity.
- **Boundaries** — Limits and expectations governing roles, contact, privacy, and responsibility.
- **Brief therapy** — Time-conscious treatment organised around focal goals and efficient change.
- **Broaching** — Inviting discussion of identity, culture, difference, and power.
- **Bullying** — Repeated harmful behaviour involving power imbalance, including online forms.
- **Burnout** — Occupational exhaustion, cynicism, and reduced efficacy associated with chronic work stress.
- **Case conceptualisation** — Collaborative formulation explaining development and maintenance of difficulties and guiding treatment.
- **Case management** — Coordination of services, referrals, and practical supports.
- **Catharsis** — Emotional release; not by itself sufficient evidence of therapeutic change.
- **Change talk** — Client language expressing desire, ability, reasons, need, commitment, activation, or steps toward change.
- **Chosen family** — Self-selected network providing kinship-like support.
- **Circadian rhythm** — Approximately daily biological cycle affecting sleep, alertness, hormones, and mood.
- **Classical conditioning** — Learning through association between stimuli.
- **Clinical formulation** — See case conceptualisation.
- **Clinical significance** — Practical importance of a change beyond statistical significance.
- **Co-regulation** — Regulation of arousal through relationship with another person.
- **Cognition** — Mental processes including attention, memory, interpretation, belief, and problem-solving.
- **Cognitive defusion** — ACT process of noticing thoughts as thoughts rather than literal commands or facts.
- **Cognitive distortion** — Biased or inaccurate pattern of interpretation; best used descriptively rather than as blame.
- **Cognitive restructuring** — Identifying, testing, and revising unhelpful appraisals or beliefs.
- **Cognitive triad** — Beck's negative view of self, world/experience, and future in depression.
- **Cohesion** — In groups or families, sense of belonging and commitment.

### Key Terms at a Glance (continued)

- **Collaborative empiricism** — CBT stance in which client and practitioner test ideas together.
- **Collective efficacy** — Shared belief that a group can organise and act effectively.
- **Common factors** — Therapeutic elements shared across models, including alliance, empathy, expectancy, goals, and feedback.
- **Communication analysis** — Detailed reconstruction of an interpersonal exchange.
- **Comorbidity** — Presence of more than one condition or difficulty at the same time.
- **Compassion** — Concern for suffering with motivation to help; in MI, prioritising client welfare.
- **Competence** — Knowledge, skill, judgement, and ethical capacity to perform a professional task.
- **Conditioned response** — Learned response to a previously neutral stimulus after association.
- **Confidentiality** — Ethical and legal duty to protect private information within stated limits.
- **Conflict (interpersonal)** — Dispute arising from incompatible goals, expectations, needs, or interpretations.
- **Congruence** — Practitioner genuineness and consistency between experience and communication.
- **Consent** — Informed, voluntary agreement by a person with legal authority and capacity for the decision.
- **Consequence** — Event following behaviour that may alter its future likelihood.
- **Containment** — Relational process by which overwhelming affect is received, tolerated, and returned in manageable form.
- **Contingency** — Relationship between behaviour and its consequences.
- **Contingency management** — Planned alteration of reinforcement and consequences in a setting.
- **Coping** — Cognitive, behavioural, emotional, relational, or spiritual-neutral strategies used to manage demands; may be helpful or costly.
- **Core belief/schema** — Deeply held general belief about self, others, or world.
- **Corrective experience** — New relational or behavioural experience that updates expectations.
- **Countertransference** — Practitioner emotional and relational responses in treatment, requiring reflection.
- **Crisis** — Situation in which demands exceed current coping or safety resources.
- **Crisis plan** — Agreed steps, contacts, and supports for periods of elevated risk.
- **Cultural formulation** — Assessment of cultural identity, explanations, context, and clinician-client differences.

## Key Terms at a Glance (continued)

- **Cultural humility** — Lifelong self-critique, openness, and accountability regarding culture and power.
- **Culture** — Shared and contested patterns of meaning, practice, identity, language, values, and institutions.
- **Defence mechanism** — Psychological strategy reducing awareness of painful affect or conflict.
- **De-escalation** — Actions that reduce arousal, threat, and likelihood of harm.
- **Deliberate self-harm** — Self-injury or self-poisoning, regardless of suicidal intent; local terminology should be used carefully.
- **Denial** — Defence involving refusal to acknowledge aspects of reality.
- **Dependence** — Reliance on a person, substance, or behaviour; developmental dependence is normal in childhood.
- **Desensitisation** — Reduced emotional response after repeated or graded contact.
- **Developmental cascade** — Effects spreading across domains and developmental periods.
- **Developmental trauma** — Impact of chronic, interpersonal adversity during development; not a stand-alone diagnosis in major manuals.
- **Diagnosis** — Classification of symptoms and patterns for communication, planning, and eligibility.
- **Dialectics** — Holding apparently opposing truths together, such as acceptance and change.
- **Differentiation of self** — Capacity to maintain self-definition while remaining emotionally connected.
- **Digital safety** — Practices reducing online exploitation, bullying, privacy loss, and harmful contact.
- **Disenfranchised grief** — Grief not socially recognised or supported.
- **Disputation** — REBT process of questioning rigid or irrational beliefs.
- **Dissociation** — Disruption in consciousness, memory, identity, perception, or sense of self, often associated with overwhelm.
- **Distress tolerance** — Capacity to endure painful states without making them worse.
- **Dorsal vagal language** — Polyvagal-informed term for shutdown-related states; theoretical claims should be taught cautiously.
- **Double bind** — Contradictory communications with limited ability to comment or escape.
- **Dropout** — Ending treatment before agreed completion; meaning should be investigated rather than assumed.

### Key Terms at a Glance (continued)

- **Dual-systems model** — Adolescent model contrasting reward sensitivity with developing cognitive control.
- **Dyad** — Two-person relationship or session format.
- **Ecological systems theory** — Bronfenbrenner's model of nested developmental contexts.
- **Efficacy (self-)** — Belief in capability for a specific task in a specific context.
- **Ego states** — In transactional analysis, Parent, Adult, and Child patterns of feeling, thinking, and behaving.
- **Emotion coaching** — Helping a person notice, name, validate, regulate, and act on emotion.
- **Emotion-focused therapy** — Treatment working with primary and secondary emotions and unmet needs.
- **Emotional cutoff** — Distancing from family relationships to manage unresolved attachment intensity.
- **Empathy** — Understanding and communicating another person's experience from their frame of reference.
- **Empowerment** — Increasing agency, voice, resources, and control.
- **Enactment** — Relational pattern expressed in action, including in therapy.
- **Engagement** — Process of establishing participation and working relationship.
- **Epistemic trust** — Openness to learning from another as a trustworthy source of social knowledge.
- **Escape-maintained behaviour** — Behaviour maintained by removing or postponing demands or aversive conditions.
- **Ethics** — Principles and standards governing professional conduct.
- **Evidence-based practice** — Integration of best research evidence, clinical expertise, client preferences, and context.
- **Exception** — In solution-focused work, a time when the problem is absent, weaker, or handled differently.
- **Exposure** — Planned contact with feared stimuli or memories under conditions that permit new learning.
- **Externalisation** — Narrative practice separating person from problem so the problem's influence can be examined.
- **Extinction** — Reduction of behaviour when reinforcement is withheld; may involve an initial burst.

## Key Terms at a Glance (continued)

- **Family projection process** — Transmission of parental anxiety or unresolved issues onto a child.
- **Family systems** — Patterns of interaction, structure, boundaries, and feedback in families.
- **Feedback-informed care** — Routine use of client outcome and alliance feedback to adjust treatment.
- **Feminist counselling** — Practice analysing gender, power, social context, and empowerment.
- **Fidelity** — Degree to which an intervention is delivered as intended.
- **Fight-or-flight** — Mobilising threat responses preparing confrontation or escape.
- **Flashback** — Intrusive re-experiencing of traumatic material as if occurring now.
- **Flooding** — Intense exposure approach; generally requires caution and is not first-line for most youth presentations.
- **Formulation** — See case conceptualisation.
- **Freeze** — Threat response involving immobility or shutdown.
- **Functional analysis** — Assessment of antecedents, behaviours, consequences, and maintaining functions.
- **Functional behaviour assessment** — Educational and clinical assessment of behaviour purpose and context.
- **Gender dysphoria** — Clinically significant distress associated with incongruence between experienced gender and assigned sex, as defined in diagnostic systems.
- **Gender expression** — External communication of gender through appearance, behaviour, voice, and roles.
- **Gender identity** — Internal sense of one's gender.
- **Generalisation** — Transfer of learning or behaviour change across settings, people, and time.
- **Genogram** — Family diagram showing relationships, patterns, events, and generations.
- **Goal** — Desired outcome guiding treatment; should be meaningful and reviewable.
- **Grief** — Response to loss, including emotional, bodily, cognitive, social, and behavioural dimensions.
- **Grounding** — Techniques orienting attention to present sensory reality to manage arousal or dissociation.
- **Group cohesion** — Members' sense of belonging, trust, and commitment in a group.

## Key Terms at a Glance

- **Habit reversal** — Behavioural procedure involving awareness, competing responses, and practice for repetitive behaviours.
- **Habituation** — Decreased response after repeated stimulation; not the only mechanism proposed for exposure.
- **Harm reduction** — Practical strategies reducing negative consequences of risky behaviour without requiring immediate abstinence as the only goal.
- **Hierarchy (exposure)** — Ordered list of feared situations from manageable to most difficult.
- **Hierarchy (family)** — Organisation of authority and responsibility across generations and subsystems.
- **Homeostasis** — System tendency to maintain stability, sometimes including symptom patterns.
- **Homework** — Between-session practice agreed in therapy.
- **Hyperarousal** — Excessive activation involving vigilance, startle, irritability, tension, or panic.
- **Hypoarousal** — Reduced activation involving numbness, shutdown, slowed response, or dissociation.
- **Hypermentalizing** — Overconfident, elaborate interpretation of mental states from limited evidence.
- **Hypomentalizing** — Limited reflection on mental states.
- **Identity** — Organised sense of self across time, roles, values, groups, body, and future.
- **Idiographic measure** — Measure tailored to an individual's goals or target behaviours.
- **Immediacy** — Practitioner use of here-and-now relationship experience.
- **Impulsivity** — Action with limited forethought; may reflect development, arousal, neurodivergence, substances, or context.
- **Incongruence** — Rogers' discrepancy between self-concept and experience.
- **Individuation** — Development of distinct identity and autonomy within relationships.
- **Informed consent** — Consent based on understandable information about nature, benefits, risks, alternatives, and rights.
- **Inhibitory learning** — Exposure account in which new safety learning competes with threat associations.
- **Insight** — Understanding of patterns or meanings; useful but not always sufficient for change.
- **Internal object** — Mental representation of self in relation to another, charged with affect.
- **Internal working model** — Expectations about self, others, and relationships derived from attachment experience.

## Key Terms at a Glance (continued)

- **Internalised stigma** — Applying negative social stereotypes to oneself.
- **Interpersonal inventory** — IPT assessment of important relationships and problem areas.
- **Interpersonal psychotherapy (IPT)** — Time-limited treatment targeting grief, disputes, transitions, and interpersonal deficits.
- **Intersectionality** — Framework analysing interacting identities and systems of power.
- **Intervention** — Intentional action intended to improve health, functioning, learning, or wellbeing.
- **Interview (motivational)** — See motivational interviewing.
- **Intimate partner violence** — Physical, sexual, psychological, economic, or coercive harm within intimate relationships; adolescent dating violence requires safeguarding.
- **Introjection** — Internalising another's attitudes or projections as part of self-experience.
- **Invalidation** — Communication that emotions or perceptions are wrong, excessive, or unacceptable.
- **Irrational belief (REBT)** — Rigid, illogical, or absolutist belief associated with disturbance in Ellis's model.
- **Joining** — Family therapy process of entering the family's style to build alliance and influence.
- **Joint session** — Meeting involving young person and family members or professionals together.
- **Learned helplessness** — Expectation that action cannot influence outcomes after uncontrollable aversive experience.
- **Learning theory** — Accounts of behaviour change through conditioning, observation, cognition, and environment.
- **Least restrictive intervention** — Effective option imposing the least limitation on rights and autonomy.
- **Limit setting** — Clear, proportionate boundaries for safety and therapeutic structure.
- **Listening (reflective)** — Responding that conveys understanding of content, feeling, meaning, or ambivalence.
- **Locus of control** — Beliefs about whether outcomes are mainly controlled by oneself or external forces.
- **Loss** — Loss of a person, role, place, capacity, relationship, status, or imagined future.
- **Maintenance** — Preservation of gains after active treatment.
- **Maladaptive** — Pattern that creates harm or impairment in context, even if originally protective.
- **Mandated treatment** — Treatment required by court, school, safeguarding, or another authority.

### Key Terms at a Glance (continued)

- **Marked mirroring** — Caregiver reflection that represents a child's feeling without simply reproducing it overwhelmingly.
- **Mastery experience** — Successful performance providing evidence of capability.
- **Meaning-making** — Process of constructing significance from experience.
- **Mechanism of change** — Process through which intervention produces outcome.
- **Medical model** — Framework understanding problems primarily as disorders requiring diagnosis and treatment.
- **Mental health literacy** — Knowledge and beliefs aiding recognition, management, and prevention of mental distress.
- **Mentalization** — Understanding behaviour in terms of mental states.
- **Mentalization-based treatment (MBT)** — Treatment restoring mentalizing under arousal, especially in relational difficulties.
- **Mesosystem** — Connections among a young person's immediate settings.
- **Metacognition** — Awareness and regulation of one's own thinking.
- **Metacommunication** — Communication about communication or relationship.
- **Microsystem** — Immediate environment in which a person participates.
- **Mindfulness** — Present-moment attention with openness and non-judgement; clinical adaptations vary.
- **Minority stress** — Stress from stigma, discrimination, vigilance, concealment, and internalised negativity.
- **Miracle question** — Solution-focused question imagining life after the problem is solved.
- **Modelling** — Learning or teaching through observation of behaviour and consequences.
- **Mood monitoring** — Tracking mood and related variables over time.
- **Motivational interviewing (MI)** — Collaborative conversation strengthening a person's own motivation and commitment to change.
- **Multisystemic therapy** — Intensive family- and community-based intervention for serious adolescent antisocial behaviour.
- **Narrative therapy** — Practice separating persons from problems and developing preferred stories and unique outcomes.
- **Negative reinforcement** — Removal of an aversive condition that increases a behaviour.
- **Neurodevelopmental conditions** — Conditions affecting brain development, including autism, ADHD, intellectual disability, communication and specific learning disorders.

## Key Terms at a Glance (continued)

- **Neuroplasticity** — Nervous system's capacity to change with experience.
- **Nominal group technique** — Structured method for generating and prioritising ideas.
- **Nomothetic measure** — Standardised measure enabling comparison with groups or norms.
- **Non-suicidal self-injury** — Deliberate injury without suicidal intent; intent can be mixed and must be assessed.
- **Not-knowing stance** — Curious recognition that mental states cannot be known with certainty.
- **Object relations** — Theories of internalised self–other relationship patterns.
- **Observational learning** — Learning by attending to, retaining, reproducing, and being motivated by modelled behaviour.
- **Obsessions** — Intrusive, unwanted thoughts, images, or urges.
- **Compulsions** — Repetitive behaviours or mental acts performed to reduce distress or prevent feared events.
- **Operant conditioning** — Learning through consequences of behaviour.
- **Operational definition** — Behaviour defined in observable, measurable terms.
- **Oppositional behaviour** — Argumentative, defiant, or hostile behaviour; description is not an explanation.
- **Orienting** — Sensory process of locating oneself in present environment.
- **Outcome expectation** — Belief about likely consequences of behaviour.
- **Outcome monitoring** — Repeated measurement of progress and feedback during care.
- **Overgeneralisation** — Drawing broad conclusions from limited events.
- **Panic attack** — Sudden surge of intense fear or discomfort with physical and cognitive symptoms.
- **Parentification** — Child assuming adult practical or emotional roles.
- **Parent training** — Structured support helping caregivers use effective, safe, relationship-supporting practices.
- **Partnership (MI)** — Collaborative working relationship rather than expert imposition.
- **Parts work** — Clinical language for internal subpersonalities or states; requires care not to literalise beyond client meaning and evidence.
- **Peer support** — Support from people with shared experience, in informal or organised forms.
- **Pendulation** — Moving attention between activation and resource in somatic work.
- **Perpetuating factors** — Processes maintaining a problem.

## Key Terms at a Glance (continued)

- **Person-centred therapy** — Humanistic approach based on empathy, congruence, and unconditional positive regard.
- **Personalisation** — Interpreting events as personally targeted without sufficient evidence.
- **Phobia** — Marked, persistent fear and avoidance of specific objects or situations causing impairment.
- **Physiological state** — Bodily arousal, fatigue, pain, hunger, illness, and hormonal or medication effects influencing behaviour.
- **Planned ignoring** — Deliberate withdrawal of attention from a behaviour while maintaining safety and reinforcing alternatives.
- **Positive reinforcement** — Addition of a consequence that increases behaviour.
- **Post-traumatic stress disorder (PTSD)** — Disorder following trauma involving intrusion, avoidance, altered cognition/mood, and arousal under diagnostic criteria.
- **Power differential** — Unequal authority, knowledge, age, institutional status, or resources in a relationship.
- **Precipitating factors** — Events triggering onset or escalation.
- **Predisposing factors** — Earlier vulnerabilities and contexts increasing likelihood of difficulty.
- **Pretend mode** — Mental-state talk disconnected from affect and lived experience.
- **Prevention** — Action reducing incidence, severity, or impact of problems.
- **Primary emotion** — Immediate adaptive emotional response to a need or event.
- **Privilege** — Unearned advantage linked to social position or system design.
- **Problem area (IPT)** — Focal category: grief, dispute, role transition, or interpersonal deficit.
- **Problem-solving therapy** — Structured method for defining problems, generating options, choosing, implementing, and reviewing.
- **Procedural learning** — Learning embodied in patterns of action and response rather than explicit knowledge.
- **Projection** — Attributing disowned feelings or motives to another.
- **Projective identification** — Interpersonal process in which disowned states are evoked or enacted in another.
- **Promotive factor** — Resource associated with positive outcomes across risk levels.
- **Protective factor** — Resource reducing probability or impact of adverse outcomes.
- **Protocol** — Specified sequence and procedures for an intervention.
- **Proximal goal** — Near-term goal supporting a larger distal goal.

## Key Terms at a Glance (continued)

- **Psychic equivalence** — Treating feelings or beliefs as external facts.
- **Psychodynamic** — Approaches emphasising unconscious processes, conflict, defence, development, and relational repetition.
- **Psychoeducation** — Structured information about a condition, development, treatment, or coping.
- **Psychological flexibility** — ACT capacity to remain present and act according to values despite difficult internal experiences.
- **Psychosis** — Conditions involving impaired reality testing such as delusions, hallucinations, or disorganised thinking; requires specialist assessment.
- **Punishment** — Consequence reducing behaviour; positive punishment adds aversive stimulus, negative punishment removes valued stimulus.

## Key Terms at a Glance

- **Radical behaviourism** — Skinner's philosophy treating private events as behaviour subject to functional analysis.
- **Rapport** — Harmonious connection supporting communication.
- **Rational emotive behaviour therapy (REBT)** — Ellis's approach identifying and disputing rigid beliefs and building healthier philosophies.
- **Reactivity** — Change in behaviour because it is being observed or measured.
- **Re-authoring** — Narrative development of preferred accounts using unique outcomes and values.
- **Reciprocal determinism** — Bandura's bidirectional influence among person, behaviour, and environment.
- **Recovery** — Personal process of living a meaningful life with or without continuing symptoms; also clinical symptom improvement depending on context.
- **Reflection (listening)** — Response conveying understanding of a speaker's meaning or feeling.
- **Reflective functioning** — Capacity to reflect on mental states in self and others.
- **Reformulation** — Revised formulation based on new evidence or response to intervention.
- **Refractory problem** — Problem persisting despite apparently appropriate intervention; a prompt to reformulate, not blame.
- **Regression** — Return to earlier developmental modes under stress.
- **Reinforcement** — Consequence increasing future behaviour.
- **Reinforcement schedule** — Pattern governing when consequences follow behaviour.
- **Relapse** — Return of symptoms or behaviour after improvement.
- **Relapse prevention** — Planning for warning signs, high-risk contexts, coping, and help seeking.
- **Relational frame** — Context of relationships through which behaviour and meaning are understood.
- **Reliability** — Consistency of measurement or judgement.
- **Reparation** — Making amends or repairing relational harm.
- **Resilience** — Dynamic process of adaptation under adversity supported by individual and environmental systems.
- **Resistance** — Ambivalence, disagreement, avoidance, or interaction pattern opposing change; not simply a client defect.
- **Resourcefulness** — Ability to identify and use internal and external resources.
- **Response cost** — Removal of a valued stimulus following behaviour.

## Key Terms at a Glance (continued)

- **Response prevention** — Blocking compulsive or avoidance responses during exposure-based work.
- **Restorative practice** — Voluntary processes addressing harm, accountability, and repair.
- **Risk assessment** — Structured identification and formulation of possible harms, contexts, and safeguards.
- **Risk factor** — Factor associated with increased probability of adverse outcome.
- **Role dispute** — IPT problem area involving non-reciprocal expectations in a relationship.
- **Role play** — Enactment of a situation for learning, rehearsal, or perspective taking.
- **Role transition** — IPT problem area involving change from an old role to a new one.
- **Routine outcome monitoring** — See outcome monitoring.
- **Rumination** — Repetitive, passive focus on distress and its causes or consequences.
- **Rupture (alliance)** — Strain or break in therapeutic collaboration, goals, tasks, or bond.
- **Safeguarding** — Protecting children and vulnerable people from abuse, neglect, exploitation, and harm.
- **Safety behaviour** — Action intended to prevent feared catastrophe that may maintain anxiety by blocking new learning.
- **Safety plan** — Collaborative plan identifying warning signs, coping, supports, professional help, and means safety.
- **Scaling question** — Solution-focused rating of present position, hope, confidence, or progress.
- **Schema** — Organised pattern of knowledge, belief, affect, and response.
- **Schema therapy** — Integrative therapy addressing early maladaptive schemas, coping styles, and modes.
- **School belonging** — Sense of acceptance, respect, safety, and participation at school.
- **School refusal** — Difficulty attending school associated with distress; requires functional and contextual assessment.
- **Screening** — Brief process identifying who may need fuller assessment.
- **Secondary emotion** — Emotion arising in response to a primary emotion, such as shame about anger.
- **Secure attachment** — Pattern in which care is sufficiently available and the child can use the caregiver as safe haven and secure base.
- **Secure base** — Relationship support from which exploration and learning occur.
- **Self-concept** — Organised perceptions and evaluations of oneself.

### Key Terms at a Glance (continued)

- **Self-determination** — Experience of autonomy, competence, and relatedness supporting motivation.
- **Self-efficacy** — Task- and context-specific belief in capability.
- **Self-esteem** — Global evaluation of self-worth.
- **Self-harm** — Intentional self-injury or poisoning irrespective of motive; intent and risk require assessment.
- **Self-monitoring** — Observing and recording one's behaviour, mood, thoughts, or physiology.
- **Self-regulation** — Managing attention, emotion, impulses, and behaviour toward goals and safety.
- **Self-soothing** — Strategies used to reduce distress; developmental capacity grows through co-regulation.
- **Sensorimotor** — Relating to sensation and movement.
- **Separation anxiety** — Excessive anxiety concerning separation from attachment figures or home.
- **Session rating scale** — Brief client feedback measure concerning session fit or alliance.
- **Setting event** — Broader contextual condition altering behaviour–consequence relations.
- **Sexual orientation** — Pattern of romantic, emotional, and/or sexual attraction.
- **Shame** — Painful self-conscious emotion involving perceived defectiveness or exposure.
- **Shaping** — Reinforcing successive approximations toward a target behaviour.
- **Sibling subsystem** — Family subsystem comprising siblings.
- **Significant other** — Important person in a client's relational world.
- **Single-case design** — Systematic evaluation of intervention effects with an individual over time.
- **Skill acquisition** — Learning through instruction, modelling, rehearsal, feedback, and practice.
- **Sleep hygiene** — Habits and environments supporting sleep; clinical sleep problems may require more than hygiene advice.
- **Social anxiety** — Fear of scrutiny, embarrassment, or negative evaluation in social or performance situations.
- **Social capital** — Resources available through relationships and networks.
- **Social clock** — Cultural expectations about timing of life transitions.
- **Social determinants of health** — Conditions in which people live, learn, work, and age that shape health.
- **Social learning** — Learning through observation, imitation, and vicarious consequences.

## Key Terms at a Glance (continued)

- **Social support** — Emotional, practical, informational, and companionship resources from relationships.
- **Solution-focused brief therapy** — Future-oriented approach using exceptions, scaling, goals, and client resources.
- **Somatic** — Relating to bodily experience.
- **Splitting** — Experiencing self or others in extreme all-good/all-bad terms; also team division into opposing views.
- **Stabilisation** — Phase of establishing safety, regulation, resources, and capacity before demanding processing.
- **Standardised measure** — Instrument administered and scored consistently with normative or criterion references.
- **Stepped care** — Matching intervention intensity to need and response, increasing or decreasing over time.
- **Stigma** — Social devaluation, stereotypes, prejudice, and discrimination linked to an identity or condition.
- **Stimulus** — Event or condition that may elicit or set the occasion for behaviour.
- **Strengths-based practice** — Assessment and intervention centred on capacities, resources, values, and hopes without denying harm.
- **Stress** — Response to demands perceived or experienced as exceeding resources.
- **Structural family therapy** — Minuchin's approach to subsystems, boundaries, hierarchy, and organisation.
- **Subjective units of distress (SUDS)** — Self-rating of distress, often 0–10 or 0–100.
- **Subsystem** — Part of a family system with its own roles and boundaries.
- **Suicidal ideation** — Thoughts about suicide, ranging from passive wishes to specific intent and plans; always requires contextual assessment.
- **Suicide risk formulation** — Dynamic explanation of factors, triggers, protective processes, and actions concerning suicide risk.
- **Supervision** — Professional process supporting competence, ethics, reflection, and accountability.
- **Support network** — People and organisations providing practical or emotional help.
- **Sustain talk** — Language favouring status quo or opposing a particular change.
- **Symptom** — Subjective experience or observable sign associated with distress or disorder.

## Key Terms at a Glance (continued)

- **Systemic** — Concerning interacting relationships, contexts, and feedback loops.
- **Teleological mode** — Mentalizing failure in which only visible action counts as proof of intention or care.
- **Teletherapy** — Counselling delivered through telecommunications.
- **Termination** — Ending phase or event in counselling.
- **Theory** — Organised set of concepts explaining phenomena and guiding observation or intervention.
- **Therapeutic alliance** — See alliance.
- **Therapeutic frame** — Boundaries of time, place, roles, fees where relevant, confidentiality, and contact.
- **Thought record** — Structured record of situation, thoughts, feelings, evidence, alternatives, and outcome.
- **Time-out** — Brief removal from reinforcing activity as part of a safe, planned behaviour strategy; not isolation or humiliation.
- **Titration** — Working in small doses to remain within tolerance.
- **Token economy** — System using tokens exchangeable for backup reinforcers.
- **Tolerance (window of)** — Arousal range in which a person can process, learn, and relate without overwhelm or shutdown.
- **Transactional analysis** — Berne's theory of ego states, transactions, games, scripts, and strokes.
- **Transference** — Relational expectations from earlier relationships activated in therapy.
- **Transition** — Change in role, setting, relationship, development, or status.
- **Trauma** — Experience or pattern that overwhelms coping and may produce lasting effects; definitions vary by framework.
- **Trauma-focused CBT** — Trauma-specific cognitive-behavioural treatment involving psychoeducation, regulation, narration/processing, and caregiver work.
- **Trauma-informed care** — Service approach recognising trauma prevalence and prioritising safety, trust, collaboration, empowerment, and cultural responsiveness.
- **Treatment fidelity** — See fidelity.
- **Treatment plan** — Document specifying formulation-based goals, interventions, responsibilities, measures, and review.
- **Triangle** — Three-person relational pattern in which tension between two is managed through a third.

## Key Terms at a Glance (continued)

- **Trigger** — Cue associated with emotional, bodily, behavioural, or memory responses.
- **Trust** — Expectation of reliability, honesty, benevolence, and respect.
- **Unconditional positive regard** — Rogers' non-possessive acceptance of the person.
- **Unconscious** — Mental processes outside current awareness.
- **Unique outcome** — Narrative term for events inconsistent with a problem-saturated story.
- **Universal prevention** — Intervention delivered to a whole population regardless of individual risk.
- **Validation** — Communicating that experience is understandable; not necessarily agreement with behaviour.
- **Validity** — Extent to which evidence supports interpretation and use of a measure or assessment.
- **Values** — Chosen directions or qualities guiding action.
- **Vicarious learning** — Learning by observing consequences experienced by others.
- **Vicarious trauma** — Practitioner changes resulting from empathic engagement with trauma material.
- **Visual schedule** — Pictorial or written sequence supporting predictability and independence.
- **Volition** — Capacity and experience of choosing or willing action.
- **Vulnerability** — Susceptibility to harm influenced by biology, development, relationships, and context.
- **Wellbeing** — Broad state of health, functioning, connection, meaning, and life satisfaction.
- **Withdrawal (social)** — Reduced participation in relationships or activities.
- **Withdrawal (substance)** — Physiological and psychological effects after reducing or stopping a substance.
- **Working alliance** — See alliance.
- **Working memory** — System for temporarily holding and manipulating information.
- **Wraparound care** — Coordinated, family-driven planning across services and natural supports.
- **Youth voice** — Meaningful participation of young people in decisions affecting them.
- **Zone of proximal development** — Vygotsky's range between independent performance and performance possible with support.

CHAPTER APPENDIX E

# Annotated Bibliography

Foundational works, contemporary reviews, and reading pathways.

This bibliography is a reading pathway, not a claim that every listed work is equally current or uncontested. Students should read primary texts alongside systematic reviews and critical literature.

## Foundations and Professional Practice

**Beck, J. S. (2020). *Cognitive Behavior Therapy: Basics and Beyond* (3rd ed.).** A clear clinical exposition of cognitive conceptualisation, session structure, and interventions. Best read as a treatment manual rather than a complete account of adolescent development.

**Carr, A. (2016). *The Handbook of Child and Adolescent Clinical Psychology* (3rd ed.).** A broad reference covering development, assessment, disorders, family contexts, and interventions. Useful for placing CAC. 701 theories in a wider clinical landscape.

**Corey, G. (2024). *Theory and Practice of Counseling and Psychotherapy* (11th ed.).** Accessible comparative introduction. Students should move from this survey to primary and evidence-focused sources.

**Johnstone, L., & Dallos, R. (Eds.). (2014). *Formulation in Psychology and Psychotherapy* (2nd ed.).** Cross-theoretical essays on formulation, power, narrative, and clinical judgement. Particularly valuable for Chapters 51–53.

**Kazdin, A. E. (2008). *Parent Management Training*.** A foundational account of behavioural parent training, treatment design, and evidence for disruptive behaviour.

**Norcross, J. C., & Goldfried, M. R. (Eds.). (2019). *Handbook of Psychotherapy Integration* (3rd ed.).** Comprehensive treatment of theoretical integration, eclecticism, common factors, and assimilative approaches. Use with Chapter 51.

**Prochaska, J. O., & Norcross, J. C. (2018). *Systems of Psychotherapy* (9th ed.).** Comparative theory text linking models to transtheoretical processes of change.

**Wampold, B. E., & Imel, Z. E. (2015). *The Great Psychotherapy Debate* (2nd ed.).** Major statement of common factors and contextual model. Read critically alongside disorder-specific treatment research.

**Weisz, J. R., & Kazdin, A. E. (Eds.). (2017). *Evidence-Based Psychotherapies for Children and Adolescents* (3rd ed.).** Essential evidence reference for youth treatments, moderators, implementation, and research limitations.

## Humanistic, Existential, Gestalt, and Narrative Works

**Cooper, M. (2008). *Essential Research Findings in Counselling and Psychotherapy*.** Helpful synthesis on relationship, client resources, and pluralistic practice.

**Epston, D., & White, M. (1992). *Experience, Contradiction, Narrative and Imagination*.** Selected papers showing narrative practice as conversation, documentation, and social action.

**Gendlin, E. T. (1978). *Focusing*.** Primary account of felt sense and experiential listening. Pair with contemporary evidence reviews rather than treating experiential report as outcome evidence.

**Mearns, D., Thorne, B., & McLeod, J. (2013). *Person-Centred Counselling in Action* (4th ed.).** Practical and relational account of Rogers' approach with attention to practitioner use of self.

**Perls, F., Hefferline, R., & Goodman, P. (1951). *Gestalt Therapy*.** Foundational but historically situated. Contemporary trauma and cultural critiques should inform use of experiments.

**Rogers, C. R. (1951). *Client-Centered Therapy*.** Primary source for the therapeutic conditions and client-directed change.

**Rogers, C. R. (1961). *On Becoming a Person*.** Accessible essays on self, relationships, education, and becoming. Useful for teaching but not a substitute for outcome research.

**White, M. (2007). *Maps of Narrative Practice*.** Mature exposition of externalising conversations, re-authoring, unique outcomes, and definitional ceremonies.

**White, M., & Epston, D. (1990). *Narrative Means to Therapeutic Ends*.** Foundational narrative text. Read with attention to power, discourse, and the social contexts of stories.

**Yalom, I. D. (1980). *Existential Psychotherapy*.** Classic organisation around death, freedom, isolation, and meaninglessness. Developmentally adapt before applying to younger adolescents.

## Cognitive and Third-Wave Works

**Beck, A. T. (1976). *Cognitive Therapy and the Emotional Disorders*.** Historical foundation of cognitive therapy and the cognitive model.

**Beck, A. T., Rush, A. J., Shaw, B. F., & Emery, G. (1979). *Cognitive Therapy of Depression*.** Primary treatment text whose session methods remain influential.

**Ellis, A. (1962). *Reason and Emotion in Psychotherapy*.** Foundational REBT statement. Students should compare its confrontational heritage with collaborative contemporary practice.

**Hayes, S. C., Strosahl, K. D., & Wilson, K. G. (2012). *Acceptance and Commitment Therapy* (2nd ed.).** Comprehensive ACT account including relational frame theory, psychological flexibility, values, and clinical methods.

**Kendall, P. C. (Ed.). (2012). *Child and Adolescent Therapy: Cognitive-Behavioral Procedures* (4th ed.).** Developmental CBT methods, anxiety programmes, family involvement, and school applications.

**Linehan, M. M. (2015). *DBT Skills Training Manual* (2nd ed.).** Core skills curriculum. Adolescent adaptations and family components should be studied before use.

**Miller, A. L., Rathus, J. H., & Linehan, M. M. (2007). *Dialectical Behavior Therapy with Suicidal Adolescents*.** Key adolescent DBT adaptation addressing self-harm, family involvement, and treatment structure.

**Segal, Z. V., Williams, J. M. G., & Teasdale, J. D. (2018). *Mindfulness-Based Cognitive Therapy for Depression* (2nd ed.).** Main MBCT text, including relapse prevention and inquiry. Adapt cautiously for adolescents and trauma presentations.

**Young, J. E., Klosko, J. S., & Weishaar, M. E. (2003). *Schema Therapy*.** Primary guide to schemas, coping styles, and modes. Useful where chronic interpersonal patterns persist.

## Behavioural and Learning Works

**Bandura, A. (1977). *Social Learning Theory*.** Foundational statement on modelling and vicarious learning.

**Bandura, A. (1997). *Self-Efficacy: The Exercise of Control*.** Comprehensive treatment of efficacy beliefs across development, health, education, and collective action.

**Cooper, J. O., Heron, T. E., & Heward, W. L. (2020). *Applied Behavior Analysis* (3rd ed.).** Detailed ABA reference. Read with disability ethics, assent, and historical critiques.

**Ferster, C. B., & Skinner, B. F. (1957). *Schedules of Reinforcement*.** Primary experimental source, historically important though not a clinical manual.

**Iwata, B. A., et al. (1994).** Research programme on functional analysis of self-injurious behaviour. Important for understanding experimental functional analysis and its constraints.

**Kazdin, A. E. (2005). *Parent Management Training*.** Evidence and procedures for changing coercive cycles and building positive parenting practices.

**Maag, J. W. (2018). *Behavior Management: From Theoretical Implications to Practical Applications* (3rd ed.).** School-oriented behavioural practice with functional and ethical dimensions.

**Martell, C. R., Dimidjian, S., & Herman-Dunn, R. (2022). *Behavioral Activation for Depression* (2nd ed.).** Clear behavioural activation manual applicable with developmental adaptation.

**Skinner, B. F. (1953). *Science and Human Behavior*.** Core radical behaviourist account. Pair with contemporary critiques and cognitive, cultural, and relational developments.

**Wolpe, J. (1958). *Psychotherapy by Reciprocal Inhibition*.** Historical source for systematic desensitisation and behavioural treatment of fear.

## Family, Attachment, and Interpersonal Works

**Ainsworth, M. D. S., Blehar, M. C., Waters, E., & Wall, S. (1978). *Patterns of Attachment*.** Foundational strange situation research. Read with cross-cultural critiques.

**Asen, E., & Fonagy, P. (2021). *Mentalization-Based Treatment with Families*.** Practical family MBT using curiosity, affect, perspective taking, and network meetings.

**Bowlby, J. (1988). *A Secure Base*.** Clinically accessible attachment essays on caregiving, loss, and therapeutic relationships.

**Goldenberg, I., Stanton, M., & Goldenberg, H. (2017). *Family Therapy: An Overview* (9th ed.).** Broad family therapy survey with models, techniques, and research.

**Haley, J. (1976). *Problem-Solving Therapy*.** Strategic family therapy text historically important for directives, hierarchy, and sequences.

**McGoldrick, M., Gerson, R., & Petry, S. (2008). *Genograms: Assessment and Intervention* (3rd ed.).** Practical guide to family diagrams and intergenerational patterns.

**Minuchin, S. (1974). *Families and Family Therapy*.** Foundational structural family therapy text.

**Mufson, L., Dorta, K. P., Moreau, D., & Weissman, M. M. (2011). *Interpersonal Psychotherapy for Depressed Adolescents* (2nd ed.).** Main IPT-A manual linking depression to grief, disputes, transitions, and deficits.

**Weissman, M. M., Markowitz, J. C., & Klerman, G. L. (2017). *The Guide to Interpersonal Psychotherapy* (updated ed.).** Concise IPT overview across applications.

## Trauma, Emotion, and Somatic Works

**Cohen, J. A., Mannarino, A. P., & Deblinger, E. (2017). *Treating Trauma and Traumatic Grief in Children and Adolescents* (2nd ed.).** Core TF-CBT text with caregiver components and developmental adaptations.

**Dana, D. (2018). *The Polyvagal Theory in Therapy*.** Clinically accessible polyvagal-informed exercises and language. Pair with scientific critiques of polyvagal claims.

**Greenberg, L. S. (2015). *Emotion-Focused Therapy: Coaching Clients to Work Through Their Feelings* (2nd ed.).** Updated EFT account of emotion schemes, markers, and tasks.

**Herman, J. L. (2015). *Trauma and Recovery* (2015 ed.).** Influential phase-oriented and political account of trauma, safety, remembrance, and reconnection.

**Ogden, P., & Fisher, J. (2015). *Sensorimotor Psychotherapy*.** Clinical methods for tracking sensation, posture, movement, and procedural patterns.

**Porges, S. W. (2011). *The Polyvagal Theory*.** Primary theoretical source. Students should also read critiques and current autonomic science.

**Shapiro, F. (2018). *Eye Movement Desensitization and Reprocessing (EMDR) Therapy* (3rd ed.).** Main EMDR text. Use certified training and child protocols before clinical delivery.

**van der Kolk, B. (2014). *The Body Keeps the Score*.** Influential synthesis of trauma, development, body, and treatment. Popular reach makes critical appraisal especially important.

## Child Development, Resilience, and Schools

**Blakemore, S.-J. (2018). *Inventing Ourselves*.** Accessible account of adolescent brain and social development.

**Bronfenbrenner, U. (1979). *The Ecology of Human Development*.** Primary ecological systems text.

**Dahl, R. E., Allen, N. B., Wilbrecht, L., & Suleiman, A. B. (2018).** "Importance of investing in adolescence from a developmental science perspective." *Nature, 554*, 441–450. A concise argument for adolescence as a sensitive developmental window.

**Masten, A. S. (2014). *Ordinary Magic: Resilience in Development*.** Comprehensive resilience synthesis emphasising ordinary adaptive systems.

**Steinberg, L. (2023). *Adolescence* (13th ed.).** Standard developmental text integrating biology, cognition, family, peers, school, and culture.

**Ungar, M. (2011).** "The social ecology of resilience." *American Journal of Orthopsychiatry, 81*(1), 1–17. Challenges individualistic resilience definitions.

**American School Counselor Association. (2022). *ASCA National Model* (4th ed.).** Comprehensive school counselling framework requiring local adaptation.

**Stone, C. B. (2022). *Ethics and Law for School Counselors* (5th ed.).** Detailed school confidentiality, records, and legal dilemmas.

## Culture, Feminist, Intersectional, and LGBTQ+ Practice

**American Psychological Association. (2015).** Guidelines for psychological practice with transgender and gender nonconforming people. Competencies for assessment, identity, stigma, and care systems.

**American Psychological Association. (2021).** Guidelines for psychological practice with sexual minority persons. Comprehensive affirmative practice resource.

**Crenshaw, K. (1989).** “Demarginalizing the intersection of race and sex.” Foundational intersectionality article grounded in Black feminist legal critique.

**Hook, J. N., et al. (2013).** Cultural humility research linking openness and alliance. Useful corrective to competence as static mastery.

**Meyer, I. H. (2003).** Minority stress model for lesbian, gay, and bisexual populations. Extend cautiously and intersectionally to other groups.

**Ratts, M. J., et al. (2016).** Multicultural and Social Justice Counseling Competencies. Framework linking self-awareness, client worldview, relationship, and advocacy.

**Ryan, C., et al. (2009).** Family rejection and health outcomes research. Pair with Family Acceptance Project practice materials.

**Sue, D. W., Sue, D., Neville, H. A., & Smith, L. (2022). *Counseling the Culturally Diverse* (9th ed.).** Major multicultural counselling text; read with attention to evolving terminology and evidence.

**Worell, J., & Remer, P. (2003). *Feminist Perspectives in Therapy*.** Empowerment model integrating gender, power, and social change.

## Motivational, Assessment, and Outcome Works

**Hunsley, J., & Mash, E. J. (Eds.). (2018). *A Guide to Assessments that Work* (2nd ed.).** Evidence-focused assessment across disorders and populations.

**Lambert, M. J. (2010). *Prevention of Treatment Failure*.** Outcome feedback and deterioration detection.

**Miller, W. R., & Rollnick, S. (2023). *Motivational Interviewing* (4th ed.).** Current comprehensive MI text.

**Naar, S., & Suarez, M. (2021). *Motivational Interviewing with Adolescents and Young Adults* (2nd ed.).** Developmental, family, and systems adaptations.

**Rollnick, S., Kaplan, S. G., & Rutschman, R. (2016). *Motivational Interviewing in Schools*.** Brief conversations for attendance, behaviour, learning, and health.

## Research and Teaching Works

**Ambrose, S. A., et al. (2010). *How Learning Works*.** Seven research-based principles for teaching.

**Biggs, J., & Tang, C. (2011). *Teaching for Quality Learning at University* (4th ed.).** Constructive alignment and assessment design.

**Brookfield, S. D. (2017). *Becoming a Critically Reflective Teacher* (2nd ed.).** Power, student perception, and reflective teaching.

**Hattie, J., & Timperley, H. (2007).** “The power of feedback.” *Review of Educational Research, 77*(1), 81–112. Distinguishes feedback about task, process, self-regulation, and self.

**Weisz, J. R., et al. (2017).** Youth psychotherapy evidence syntheses and meta-analyses. Important for understanding modest average effects, heterogeneity, and implementation.

## Chapter-by-Chapter Study Notes

The following notes help students connect the bibliography to seminar work. For each chapter, identify one primary source, one evidence source, and one critical or youth-specific source. Do not treat a classic text as current evidence merely because it is historically important.

**Chapter 1: The Role of Theory in Professional Counseling Practice.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 2: Scientific and Professional Foundations of Counseling.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 3: Philosophical Worldviews: The Five Domains of Theory.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 4: A Genealogy of Counseling Theories.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 5: The Therapeutic Relationship: Alliance, Rupture, and Repair.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source

that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 6: Common Factors, Placebo Effects, and Specific Factors.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 7: The Evidence Base: Evaluating Counseling Theories.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 8: Culturally Responsive Theory and the Cultural Lens.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 9: Developmental Foundations for Counseling Youth.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 10: Person-Centered Theory: The Client as Expert.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 11: Existential Therapy: Meaning, Isolation, and Freedom.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar,

students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 12: Gestalt Therapy: Awareness, Contact, and the Here and Now.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 13: Focusing-Oriented Therapy and the Felt Sense.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 14: Transactional Analysis: Structure, Strategy, and Script.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 15: Internal Family Systems and Structural Dissociation.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 16: Cognitive Therapy: The Cognitive Model.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 17: Cognitive Therapy with Children and Adolescents.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and

one decision they would monitor locally if using the approach.

**Chapter 18: Rational Emotive Behavior Therapy.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 19: Schema Therapy: Modes, Styles, and Early Maladaptive Schemas.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 20: Acceptance and Commitment Therapy.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 21: Dialectical Behavior Therapy and Its Adolescent Adaptations.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 22: Mindfulness-Based Cognitive Therapy and Mindfulness Approaches.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 23: Behavior Therapy: Principles of Learning.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 24: Applied Behavior Analysis: Functional Assessment.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 25: Exposure, Modeling, and Behavioral Skills Training.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 26: Operant Conditioning and Contingency Management.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 27: Behavioral Activation and Activity Scheduling.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 28: Contingency Management in Schools and Clinics.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 29: Functional Analysis of Self-Injurious and Aggressive Behaviour.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 30: Family Systems Theory: Bowen and the Generational Project.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 31: Structural Family Therapy.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 32: Strategic Family Therapy and Communication Theory.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 33: Family Therapy with Parents and Adolescents.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 34: Attachment Theory and Attachment-Based Therapy.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 35: Solution-Focused Brief Therapy and Strength-Based Practice.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 36: Narrative Therapy and the Re-Authoring of Lives.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 37: Emotion-Focused Therapy.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 38: Trauma-Informed Practice: Principles, Phases, and Precautions.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 39: EMDR and Bilateral Stimulation.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 40: Stabilisation, Grounding, and Phase-Oriented Work.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 41: Interpersonal Psychotherapy for Adolescents.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 42: Mentalization-Based Treatment.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 43: Somatic, Sensorimotor, and Polyvagal-Informed Practice.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 44: Motivational Interviewing.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 45: Social Cognitive Learning Theory.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 46: Adolescent Development: Theory and Counseling Implications.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 47: Psychodynamic and Object Relations Approaches.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 48: Multicultural, Feminist, and Intersectional Theory.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 49: Affirmative Practice with LGBTQ+ Youth.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 50: Resilience, Ecological Systems, and Strengths-Based Practice.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 51: Theoretical Integration and the Integrative Stance.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 52: Case Conceptualization and Treatment Planning.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 53: Assessment and Outcome Monitoring in Counseling.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 54: Termination, Evaluation, and the Ethics of Endings.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 55: Teletherapy and Technology in Counseling with Youth.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 56: School Counseling Practice and Consultation.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 57: Teaching CAC. 701: Session Plans and Facilitation.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

**Chapter 58: Assessment Blueprint, Assignments, and Rubrics.** Begin with the chapter's primary theorists and then locate a systematic review, guideline, or well-designed outcome study relevant to adolescents. Ask what population was studied, what comparison was used, which outcomes mattered to young people and families, and what implementation resources were assumed. Finish by finding one source that criticises the model's cultural assumptions, mechanism, or transfer from adults to youth. In seminar, students should be able to state one claim supported by the literature, one claim that remains contested, and one decision they would monitor locally if using the approach.

CHAPTER APPENDIX F

# Session and Worksheet Templates

Reusable session outlines, thought records, scales, and trackers.

## F1. Initial Session Contracting Worksheet

Young person's preferred name and safe contact method: _____

Who referred me and what I understand the reason to be: _____

What I want to be different: _____

What adults want to be different: _____

What counselling can and cannot do here: _____

What will stay private and what may need to be shared: _____

People I want involved or not involved: _____

How I can pause, stop, ask questions, or change activity: _____

How appointments, cancellations, messages, and emergencies work: ____

How we will know whether counselling is helping: _____

First review date: _____

## F2. Session Planning and Review Sheet

Session date/number: _____ Present: _____

Opening check-in and current state: _____

Young person's agenda: _____

Risk or safeguarding changes: _____

Goal focus for today: _____

Intervention and theory rationale: _____

What the young person did, said, or discovered: _____

What changed in the room: _____

Family/school/system action agreed: _____

Practice before next session: _____

Rating of usefulness (0–10) and one-point-higher change: _____

Plan for next session: _____

## F3. Five-Part Formulation Worksheet

**Presenting pattern:** When, where, with whom, how often, impact?

**Predisposing factors:** Development, temperament, health, learning, relationships, culture, prior adversity and coping.

**Precipitating factors:** Recent changes, losses, transitions, demands, conflicts.

**Perpetuating factors:** Avoidance, reinforcement, beliefs, arousal, family/school sequences, accommodation, insomnia, practical barriers, discrimination, service fragmentation.

**Protective factors:** Relationships, skills, interests, school/community resources, values, prior successes, practical assets.

**One-sentence collaborative formulation:** “When _____ happens, I tend to _____ because _____; this helps by _____ but keeps _____ going. I already have _____ that we can build on. First we will _____.”

**What would show this formulation is wrong or incomplete?** _____

## F4. ABC and Function Worksheet

Behaviour in observable words: _____

| Date/time/setting | Antecedent | Behaviour | Immediate consequence | Longer consequence |
|---|---|---|---|---|
| | | | | |
| | | | | |
| | | | | |

What may the behaviour obtain, avoid, communicate, regulate, or protect?

Possible functions to test: attention / escape / tangible or activity / sensory or automatic / communication / safety / status / other.

Safer or more effective replacement behaviour: _____

Who must change responses, and how? _____

Data to collect and review date: _____

## F5. Exposure and Mastery Ladder

Feared or avoided situation: _____

Belief/prediction to test: _____

Safety facts and genuine risks checked: _____

| Step | Situation | Predicted distress 0–10 | Actual distress | What happened? | What did I learn? |
|---|---|---|---|---|---|
| 1 | | | | | |
| 2 | | | | | |
| 3 | | | | | |
| 4 | | | | | |
| 5 | | | | | |

Support person and role: _____

Safety behaviours to reduce gradually: _____

Stopping/safety conditions: _____

Repeat and generalisation plan: _____

## F6. Behavioural Activation Weekly Planner

Activities to restore: pleasure / mastery / social / movement / rest / learning / contribution.

| Day | Time | Activity | With whom | Predicted pleasure 0–10 | Predicted mastery 0–10 | Actual pleasure | Actual mastery | Notes |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | | |
| | | | | | | | | |
| | | | | | | | | |

Smallest possible first step: _____

Obstacle most likely to appear: _____

If–then plan: If _____, then I will _____.

Adult or peer support: _____

## F7. Communication Chain Worksheet

Situation: _____

What the other person said/did (observable): _____

What I thought it meant: _____

Feeling(s) and body sensations: _____

What I wanted or needed: _____

What I said/did, including tone and timing: _____

What the other person may have thought it meant: _____

What happened next: _____

What I want them to understand: _____

One sentence I could try: _____

Support, timing, place, and pause plan: _____

## F8. Problem-Solving Worksheet

Problem in specific words: _____

What I can influence / cannot influence / need help with: _____

Goal for a good-enough outcome: _____

Options without judging them yet:

1. _____
2. _____
3. _____
4. _____

For the two most promising options, list likely benefits, costs, risks, and who is affected.

Option chosen and first small step: _____

Who needs to know or help? _____

When will I review what happened? _____

What I learned even if it did not work: _____

## F9. Coping and Grounding Menu

My early warning signs in body, thoughts, feelings, and behaviour:

_____

Things that help when arousal is rising:

- Movement: _____
- Sensory grounding: _____
- Breathing or voice: _____
- Place or object: _____
- Person to contact: _____
- Words that help me: _____

Things that help when I shut down or feel blank:

_____

Things that usually make it worse: _____

What adults can do that helps: _____

What adults should avoid: _____

When to seek urgent help: _____

## F10. Personal Safety Plan

This plan supplements, and does not replace, professional risk assessment and local crisis procedures.

Warning signs that a crisis may be developing: _____

Internal coping strategies I can try without harming myself: _____

People or places that provide distraction or support: _____

People I can ask for help: _____

Professionals/services and contact details: _____

Steps to make the environment safer, including limiting access to means discussed with a responsible professional: _____

What adults should do if they are worried: _____

What I want adults not to do unless safety requires it: _____

Reasons for living, people, hopes, or commitments that matter to me: _

Plan created with: _____ Date: _____ Review: _____

## F11. Family Meeting Preparation Sheet

Purpose of meeting in one sentence: _____

Young person's three priorities:

1. _____
2. _____
3. _____

Parent/carer priorities: _____

School or professional priorities, if relevant: _____

Topics not to discuss in joint session and why: _____

One recent example to examine slowly: _____

Requests each person wants to make: _____

Agreements we hope to leave with: _____

Who will write and share the summary? _____

Review date: _____

## F12. Goal Review and Ending Worksheet

Original goals: _____

What has changed in symptoms, functioning, relationships, school participation, and daily life? _____

Which changes matter most to me? _____

What helped most? _____

What did not help or felt harmful? _____

Skills and supports I will keep using: _____

Early warning signs of setback: _____

First three steps if difficulties return: _____

People and services I can contact: _____

What remains unfinished and where it can be addressed: _____

Do I want a booster, transfer, or no further counselling now? _____

Closing summary agreed and copies: _____

CHAPTER APPENDIX G

# Supervision and Reflection Templates

Structured instruments for supervision, consultation, and reflective practice.

## G1. Purpose of Supervision

Supervision protects clients, develops practitioners, and sustains ethical judgement. It is not case gossip, managerial surveillance alone, or a place to obtain permission for decisions the practitioner remains responsible for making. Good supervision integrates clinical formulation, intervention skills, relationship processes, culture and power, risk, organisational context, and practitioner wellbeing.

Students should prepare cases before supervision and identify the decision or uncertainty they are bringing. “Tell me what to do” is less useful than “I am caught between protecting confidentiality and involving a parent; here are the facts, risks, options, and my current leaning.”

## G2. Case Presentation Template

Client identifier and age band: _____

Service context and mandate: _____

Referral question and who defined it: _____

Young person's goals in their words: _____

Presenting pattern and settings: _____

Relevant development, health, learning, culture, family, peers, school, digital and material context: _____

Strengths and resources: _____

Risk, safeguarding, and protective factors: _____

Current formulation (five-part if useful): _____

Theory/interventions used and response: _____

Outcome data and client feedback: _____

Relationship processes, ruptures, practitioner reactions: _____

Ethical, cultural, legal, or organisational tensions: _____

Specific supervision question: _____

Options considered and provisional decision: _____

Actions agreed, owner, and date: _____

## G3. Reflective Practice Prompts

After a session, consider:

- What did I notice first, and what did I not notice?
- Whose language dominated my formulation—the young person's, parent's, school's, theory's, or mine?
- What did I feel in my body, and how did it influence pace or intervention?
- Where did I rush to fix, rescue, withdraw, confront, or please?
- What cultural or power assumption may have shaped my reading?

- What did the young person teach me about what helps?
- What would I do differently with the same information?
- What do I need to learn, read, practise, or refer?
- Is there a record, safeguarding, consent, or follow-up action outstanding?

Reflection is incomplete if it produces only self-criticism. It should produce a testable change in attention, behaviour, or systems.

## G4. Alliance Rupture Review

Session/date: _____

What was the rupture signal—withdrawal, confrontation, missed session, silence, compliance without engagement, sudden deterioration?

What happened immediately before it?

What might the young person have experienced?

What was my contribution?

What repair was attempted and how did it land?

What confidentiality, family, cultural, or institutional factor was involved?

What will I do at the next contact?

What supervision or team action is needed?

## G5. Risk Review Template

Current concern and time frame: _____

Static/history factors: _____

Dynamic factors and triggers: _____

Warning signs and likely scenarios: _____

Protective factors and reasons for living/engaging: _____

Young person's view and preferred help: _____

Family/school/service safeguards: _____

Actions taken, by whom, and when: _____

Information shared and basis: _____

Review trigger and date: _____

Risk formulation should be updated when circumstances change. Avoid copying forward “low risk” without fresh evidence.

## G6. Practitioner Wellbeing and Caseload Review

Current caseload complexity: _____

Cases involving death, trauma, conflict, or moral distress: _____

Sleep, workload, supervision access, and recovery time: _____

Signs of compassion fatigue, secondary traumatic stress, cynicism, over-involvement, or avoidance: _____

Supports and boundaries to strengthen: _____

Organisational changes to request: _____

Learning or referral decision arising from limits: _____

Wellbeing work is not individual resilience training alone. Unsafe staffing, impossible caseloads, poor supervision, and discriminatory workplaces require organisational action.

## G7. Individual Supervision Agenda

1. Immediate safety, safeguarding, legal, or ethical issues.
2. Cases with deterioration, rupture, or uncertainty.
3. One case presented in depth.
4. Skills observation or transcript review.
5. Cultural, power, and practitioner-position reflection.
6. Service constraints and advocacy.
7. Learning actions and reading.
8. Practitioner wellbeing and boundaries.
9. Review of previous actions.

Supervision record: date, attendees, cases by identifier, decisions, rationale, actions, review dates. Store supervision records according to policy, separate from client notes where required.

## G8. Group Supervision Protocol

A 90-minute group might include:

- five minutes: urgent risk or ethical notices;
- twenty minutes: Case A presentation and clarifying questions;
- fifteen minutes: multiple theoretical readings;
- ten minutes: agreed actions;
- twenty minutes: Case B skills transcript or recording (with consent);
- fifteen minutes: systems and equity theme;
- five minutes: learning commitments.

Ground rules: confidentiality within lawful limits, no identifiable information beyond need, curiosity before advice, challenge ideas not people, no requirement to disclose personal trauma, and explicit attention to whose perspective is missing.

## G9. Peer Observation Feedback Form

Observed capability and context: _____

Consent and contracting observed: _____

Strengths with behavioural evidence:

1. _____
2. _____
3. _____

Moments where practice was effective: _____

Moment requiring development and exact alternative wording/action: ____

Developmental and cultural responsiveness: _____

Safety, boundaries, and ethics: _____

One priority for next practice: _____

Observer signature/date: _____ Practitioner response: _____

## G10. Reflective Essay Structure

Use this structure for assessed reflection without disclosing unnecessary personal or client material.

**Situation.** Briefly describe the event using fictional or properly anonymised material.

**Observation.** Separate facts, feelings, bodily responses, and interpretations.

**Theory.** Apply at least two concepts from the course and identify where they conflict.

**Culture and power.** Examine identity, institutional position, language, and whose knowledge was privileged.

**Ethics.** Identify duties, consent, confidentiality, safeguarding, and boundaries.

**Learning.** State what changed in your understanding, with evidence.

**Action.** Specify one practice change, one learning activity, and one supervision question.

**Evaluation.** How will you know whether the change helped a future client?

## G11. Monthly Practitioner Development Log

| Date | Capability practised | Source/supervision | Client or simulated context | Evidence of change | Next step |
|---|---|---|---|---|---|
| | | | | | |
| | | | | | |
| | | | | | |

Competence should be claimed narrowly. “Completed a workshop” is exposure; “delivered under supervision with fidelity and reviewed outcomes” is stronger evidence.

## G12. Difficult Supervision Questions

- What am I avoiding asking this client or family?
- Which theory am I using to protect myself from uncertainty?
- Who would describe this case completely differently?
- What if the problem is the service arrangement, not the young person?
- Am I continuing because it helps, because ending feels like rejection, or because the system rewards activity?
- What would I do if this were my last session?
- What evidence would make me refer, escalate, or stop?
- Whose voice has not been heard directly?
- What is the smallest ethical action available today?

## Chapter-Linked Supervision Prompts

Select the prompt corresponding to the model being used. Bring evidence from a session, record, measure, or observed interaction rather than only a general impression.

**Chapter 1 — The Role of Theory in Professional Counseling Practice:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 2 — Scientific and Professional Foundations of Counseling:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 3 — Philosophical Worldviews: The Five Domains of Theory:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 4 — A Genealogy of Counseling Theories:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 5 — The Therapeutic Relationship: Alliance, Rupture, and Repair:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 6 — Common Factors, Placebo Effects, and Specific Factors:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 7 — The Evidence Base: Evaluating Counseling Theories:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 8 — Culturally Responsive Theory and the Cultural Lens:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 9 — Developmental Foundations for Counseling Youth:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 10 — Person-Centered Theory: The Client as Expert:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 11 — Existential Therapy: Meaning, Isolation, and Freedom:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 12 — Gestalt Therapy: Awareness, Contact, and the Here and Now:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 13 — Focusing-Oriented Therapy and the Felt Sense:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 14 — Transactional Analysis: Structure, Strategy, and Script:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 15 — Internal Family Systems and Structural Dissociation:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 16 — Cognitive Therapy: The Cognitive Model:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 17 — Cognitive Therapy with Children and Adolescents:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 18 — Rational Emotive Behavior Therapy:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 19 — Schema Therapy: Modes, Styles, and Early Maladaptive Schemas:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 20 — Acceptance and Commitment Therapy:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 21 — Dialectical Behavior Therapy and Its Adolescent Adaptations:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 22 — Mindfulness-Based Cognitive Therapy and Mindfulness Approaches:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 23 — Behavior Therapy: Principles of Learning:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 24 — Applied Behavior Analysis: Functional Assessment:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 25 — Exposure, Modeling, and Behavioral Skills Training:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 26 — Operant Conditioning and Contingency Management:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 27 — Behavioral Activation and Activity Scheduling:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 28 — Contingency Management in Schools and Clinics:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 29 — Functional Analysis of Self-Injurious and Aggressive Behaviour:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 30 — Family Systems Theory: Bowen and the Generational Project:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 31 — Structural Family Therapy:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 32 — Strategic Family Therapy and Communication Theory:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 33 — Family Therapy with Parents and Adolescents:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 34 — Attachment Theory and Attachment-Based Therapy:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 35 — Solution-Focused Brief Therapy and Strength-Based Practice:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 36 — Narrative Therapy and the Re-Authoring of Lives:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 37 — Emotion-Focused Therapy:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 38 — Trauma-Informed Practice: Principles, Phases, and Precautions:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 39 — EMDR and Bilateral Stimulation:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 40 — Stabilisation, Grounding, and Phase-Oriented Work:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 41 — Interpersonal Psychotherapy for Adolescents:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 42 — Mentalization-Based Treatment:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 43 — Somatic, Sensorimotor, and Polyvagal-Informed Practice:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 44 — Motivational Interviewing:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 45 — Social Cognitive Learning Theory:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 46 — Adolescent Development: Theory and Counseling Implications:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 47 — Psychodynamic and Object Relations Approaches:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 48 — Multicultural, Feminist, and Intersectional Theory:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 49 — Affirmative Practice with LGBTQ+ Youth:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 50 — Resilience, Ecological Systems, and Strengths-Based Practice:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 51 — Theoretical Integration and the Integrative Stance:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 52 — Case Conceptualization and Treatment Planning:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 53 — Assessment and Outcome Monitoring in Counseling:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 54 — Termination, Evaluation, and the Ethics of Endings:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 55 — Teletherapy and Technology in Counseling with Youth:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 56 — School Counseling Practice and Consultation:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 57 — Teaching CAC. 701: Session Plans and Facilitation:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

**Chapter 58 — Assessment Blueprint, Assignments, and Rubrics:** What did the young person understand the purpose of the work to be? Which concept from this approach most influenced your intervention, and what exactly did you do differently because of it? What evidence supports the formulation, what evidence is missing, and what alternative explanation remains plausible? Identify the developmental, cultural, family, school, and safeguarding implications. State one moment where your own reaction may have altered the session, one limit of competence, and the specific outcome you will review next time.

CHAPTER APPENDIX H

# Referral, Documentation, and Crisis Resources

Referral mapping, documentation standards, and safety planning.

# H1. Principles for Referral

Referral is a clinical intervention, not disposal. A good referral matches need, urgency, competence, setting, culture and language, disability access, family logistics, and young person's preference. It includes a specific question, relevant information, consent or lawful basis, risk communication, and follow-up to confirm receipt.

Refer when needs exceed practitioner competence or scope, when medical or psychiatric assessment is required, when risk cannot be managed in the setting, when specialist treatment is indicated, when conflict of interest arises, or when the young person requests another service and it is clinically appropriate.

Do not refer merely because a case is complex, unrewarding, culturally unfamiliar, or likely to affect outcome statistics. Complexity may require consultation and joint work rather than transfer.

# H2. Referral Decision Checklist

- What decision or treatment can the receiving service provide that this service cannot?
- How urgent is it, and what must happen while waiting?
- Has medical assessment been considered?
- What safeguarding route applies?
- What does the young person want, fear, or expect from referral?
- What information is necessary, and what consent or lawful basis supports sharing?
- Which language, communication, disability, transport, cost, and digital access arrangements are needed?
- Who owns follow-up if the referral is rejected, delayed, or lost?
- How will current support continue during transition?
- What feedback loop will confirm attendance, assessment, and plan?

# H3. Common Referral Pathways

**Primary care/medical:** unexplained physical symptoms, pain, sleep disorders, eating and growth concerns, medication questions, puberty concerns, chronic illness, injury, sexual health, substance effects.

**Child and adolescent mental health services:** moderate to severe mental health difficulties, diagnostic complexity, self-harm, trauma symptoms, eating disorders, psychosis, severe anxiety or depression, neurodevelopmental assessment pathways.

**Emergency/crisis services:** immediate risk to life, serious injury, acute intoxication, psychosis with danger, inability to maintain safety. Use local emergency numbers and procedures.

**Safeguarding/children's social care:** suspected abuse, neglect, exploitation, trafficking, domestic abuse, unsafe care arrangements, missing episodes, serious welfare concerns.

**Education services:** special educational needs, disability accommodations, attendance, exclusion prevention, educational psychology, alternative provision, speech and language, occupational therapy.

**Substance services:** harmful use, dependence, withdrawal risk, drug-related exploitation, family support.

**Sexual health and exploitation services:** contraception, STI testing, pregnancy options under local law, sexual assault care, online exploitation, healthy relationships.

**Housing and family support:** homelessness, eviction, young caring, benefits, food insecurity, domestic abuse support, respite.

**Youth and community services:** mentoring, sport, arts, culturally specific support, LGBTQ+ youth support, disability groups, bereavement support, young carer services.

Local names, thresholds, and contact details must be inserted by each service and reviewed regularly.

## H4. Warm Handover Script

"I want to explain why I am suggesting this referral and what will happen next. Your counselling here does not have to end abruptly unless that is the service rule, and I will tell you if it does. The specialist service can help with _____. I recommend it because _____. Alternatives include _____. The referral will say _____ and will not include _____, except for safety information I have explained. You can tell me if any wording is factually wrong. I will check on _____ date whether they received it. While we wait, our plan is _____. If things become unsafe, contact _____."

Where the young person disagrees, document their view, assess capacity and risk, explain any duty to proceed, and preserve choices over timing, advocate, language, and information where possible.

## H5. Crisis Resource Card Template

Services should replace bracketed fields with verified local information and review the card at least annually.

**If there is immediate danger to life:** [local emergency number]

**24-hour crisis line:** [name, number, text/web options]

**Child protection/safeguarding:** [local route]

**Sexual assault support:** [service]

**Domestic abuse support:** [service]

**Substance emergency/poison information:** [service]

**LGBTQ+ youth support:** [service]

**Bereavement support:** [service]

**Housing emergency:** [service]

**My trusted adult:** _____ Phone: _____

**My counsellor/service and hours:** _____

**My safety plan is located:** _____

A crisis card is useful only if the young person can access it privately and believes the services will respond. Check phone credit, shared-device privacy, language, disability access, and whether contacting a service could alert an unsafe person.

## H6. Documentation Standards

Documentation should be timely, factual, proportionate, and respectful. Separate observation, report, inference, decision, and action. Record consent, information sharing, risk formulation, and review dates. Avoid jargon and moral labels.

Useful records include:

- referral and consent;
- assessment and formulation;
- treatment plan;
- session summaries;
- risk and safety plans;
- parent, school, and inter-agency contacts;
- measures and reviews;
- incidents and safeguarding actions;
- endings, referrals, and closing summaries.

Do not record speculation as fact, copy old conclusions without review, or include unnecessary information about third parties. Remember that young people and families may later read records; respectful writing is both an ethical and relational practice.

## H7. Immediate Crisis Response Sequence

This sequence supports professional judgement and local emergency procedures; it does not replace them.

1. **Ensure immediate safety.** Reduce access to means where possible, involve responsible adults or emergency services, and do not leave a young person alone if policy and risk require continuous support.
2. **Use a calm, direct approach.** Ask clearly about thoughts, intent, plans, means, intoxication, injuries, and immediate supports.
3. **Obtain medical help** for injury, ingestion, overdose, severe agitation, psychosis, or physical deterioration.
4. **Contact safeguarding and emergency supports** according to law and policy.
5. **Limit information sharing** to what is needed for protection, while being honest with the young person where safe.
6. **Document** times, observations, statements, actions, consultations, and handovers.
7. **Arrange follow-up** before the young person leaves the practitioner's responsibility. A referral sent is not a risk managed.
8. **Support staff and family**, review the response, and update the plan.

Do not ask a young person to promise never to self-harm as a substitute for assessment and safety planning. “No-suicide contracts” are not evidence-based protections.

## H8. Post-Crisis Review

Within an appropriate period after a crisis, review:

- What happened, in sequence?
- What warning signs were present or missed?
- What helped and what increased distress?
- Were confidentiality, dignity, culture, disability, and language handled well?
- Were family, school, health, and safeguarding communications timely?
- Was any restrictive intervention used, and was it lawful, proportionate, documented, and reviewed?
- What needs to change in the safety plan, environment, staffing, or referral route?
- Does the young person want a debrief, repair conversation, advocate, or complaint route?
- What support do involved staff need?

Post-crisis learning should improve systems without converting a frightened young person into a case study without consent.

## H9. Service Directory Worksheet

| Need | Local service | Eligibility | Contact | Referral route | Waiting time | Access/language notes | Verified date |
|---|---|---|---|---|---|---|---|
| Crisis | | | | | | | |
| Mental health | | | | | | | |
| Safeguarding | | | | | | | |
| Medical | | | | | | | |
| Eating concerns | | | | | | | |
| Substance use | | | | | | | |
| Sexual health/assault | | | | | | | |
| Housing | | | | | | | |
| Disability/SEND | | | | | | | |
| LGBTQ+ youth | | | | | | | |
| Young carers | | | | | | | |

| Need | Local service | Eligibility | Contact | Referral route | Waiting time | Access/language notes | Verified date |
|---|---|---|---|---|---|---|---|
| Bereavement | | | | | | | |

Review the directory at least every six months and after any failed referral.

## H10. Referral Tracking Log

Client identifier: _____ Referred to: _____

Date sent: _____ Sent by: _____ Consent/basis: _____

Acknowledged date: _____ Appointment offered: _____

Attended/declined/not eligible: _____

Outcome or plan received: _____

Current service continuing support: _____

Follow-up owner and next check date: _____

Reason for rejection and alternative plan: _____

## H11. Inter-Agency Meeting Record

Purpose and decisions required: _____

Attendees and roles: _____

Young person's views and how represented: _____

Family views: _____

Agreed formulation or shared facts: _____

Disagreements and uncertainties: _____

Actions, owners, dates: _____

Information-sharing agreements: _____

Risk/safety arrangements: _____

Review date: _____

## H12. Practitioner Crisis Pack Checklist

A service should maintain current, accessible information on:

- emergency and safeguarding contacts;
- designated safeguarding leads;
- local mental health crisis pathways;
- medical and sexual assault services;

- interpreter access;
- out-of-hours responsibilities;
- incident reporting;
- lone-working rules;
- remote-session emergency procedures;
- post-incident supervision and debrief;
- complaint and advocacy routes.

Practitioners should not carry the entire system in personal memory. Crisis competence is partly organisational design.

## Presentation-Specific Referral Pathways

Pathways must be localised. A referral should state the decision requested and continue support while waiting.

### Persistent school avoidance

Potential services include school leadership, attendance, health, educational psychology, mental health, family support. The referral should include attendance pattern, safety, curriculum access, health and sleep, family plan, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

### Self-harm or suicidal concern

Potential services include crisis, primary care, mental health, safeguarding where indicated. The referral should include current intent, means, injuries, protective factors, follow-up owner, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

### Suspected exploitation

Potential services include safeguarding, police or specialist services under local procedure, health, youth support. The referral should include immediate safety, locations, online evidence handled by specialists, trusted adult, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

## Eating or weight concern

Potential services include primary care/paediatrics, dietetics, eating disorder service, mental health. The referral should include growth, medical observations through clinicians, food pattern, exercise, family stress, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

## Substance-related harm

Potential services include substance service, primary care, safeguarding, youth work. The referral should include substances, frequency, withdrawal, supply, exploitation, motivation, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

## Possible neurodevelopmental need

Potential services include paediatrics, educational psychology, speech/language, occupational therapy, school SEND. The referral should include developmental history, settings, communication, sensory, learning profile, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

## Bereavement with functional decline

Potential services include school support, bereavement service, primary care, mental health if indicated. The referral should include relationship, rituals, functioning, trauma symptoms, family support, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

## Family conflict or unsafe discipline

Potential services include family support, safeguarding, mediation where safe, mental health. The referral should include violence/coercion, child voice, separate accounts, immediate safety, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person

disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

## Sexual health or assault concern

Potential services include sexual health, sexual assault service, safeguarding, primary care. The referral should include consent, timing, medical needs, forensic guidance by specialists, support person, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

## Housing or food insecurity

Potential services include housing, benefits/family support, school, community resources. The referral should include immediate accommodation, food, transport, school continuity, confidentiality, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

## Gender or sexuality-related distress and rejection

Potential services include affirming youth support, school safeguarding, family support, health pathways as requested. The referral should include chosen language, outness by context, bullying, home safety, support network, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

## Chronic pain or unexplained physical symptoms

Potential services include primary care/paediatrics, school health, physiotherapy or relevant specialists, mental health in parallel. The referral should include medical assessment, functioning, sleep, school participation, symptom pattern, plus the young person's goals, communication and access needs, relevant strengths, current supports, and what has already been tried. State urgency honestly and identify who will follow up if the referral is delayed or rejected. Avoid copying entire therapy notes; share the minimum necessary for the decision. Where the young person disagrees with referral, record their view and explain any duty to proceed. A pathway is not complete until receipt is confirmed and the young person knows what happens next.

CHAPTER APPENDIX I

# Glossary of Acronyms and Course FAQ

Abbreviations used throughout the book and answers to recurring student questions.

# I1. Acronyms and Abbreviations

| Acronym | Meaning |
|---|---|
| ABA | Applied behaviour analysis |
| ABC | Antecedent–Behaviour–Consequence; also Attachment and Biobehavioral Catch-up in attachment literature |
| ACEs | Adverse childhood experiences |
| ACT | Acceptance and commitment therapy |
| ADHD | Attention-deficit/hyperactivity disorder |
| APA | American Psychological Association |
| ASD | Autism spectrum disorder (terminology varies by context) |
| BACP | British Association for Counselling and Psychotherapy |
| CBT | Cognitive-behavioural therapy |
| CFTSI | Child and Family Traumatic Stress Intervention |
| DBT | Dialectical behaviour therapy |
| DDP | Dyadic developmental psychotherapy |
| DSM | Diagnostic and Statistical Manual of Mental Disorders |
| EBP | Evidence-based practice |
| EFT | Emotion-focused therapy |
| EMDR | Eye movement desensitisation and reprocessing |
| FBA | Functional behaviour assessment |
| ICD | International Classification of Diseases |
| IPT | Interpersonal psychotherapy |
| IPT-A | Interpersonal psychotherapy for adolescents |
| LGBTQ+ | Lesbian, gay, bisexual, transgender, queer/questioning and other sexual/gender minority identities |
| MBT | Mentalization-based treatment |
| MBT-A | Mentalization-based treatment for adolescents |
| MI | Motivational interviewing |
| MBCT | Mindfulness-based cognitive therapy |
| MBSR | Mindfulness-based stress reduction |
| NCTSN | National Child Traumatic Stress Network |
| NSSI | Non-suicidal self-injury |
| OCD | Obsessive-compulsive disorder |
| PTSD | Post-traumatic stress disorder |

| Acronym | Meaning |
|---|---|
| REBT | Rational emotive behaviour therapy |
| ROM | Routine outcome monitoring |
| SAMHSA | Substance Abuse and Mental Health Services Administration (United States) |
| SEND | Special educational needs and disabilities (terminology varies by jurisdiction) |
| SFBT | Solution-focused brief therapy |
| SUDS | Subjective units of distress scale |
| TF-CBT | Trauma-focused cognitive-behavioural therapy |

Acronyms change meaning across disciplines. Define them at first use in reports and avoid using them with families without explanation.

# I2. Course FAQ for Students

## Is this textbook a substitute for supervised clinical training?

No. It provides theory, formulation frameworks, teaching activities, and templates. It does not certify competence in EMDR, trauma processing, risk management, family therapy, testing, or any regulated intervention. Students require supervised practice and must follow institutional and professional requirements.

## Why does the book include theories with uneven evidence?

Professional literacy requires understanding influential models, their mechanisms, limitations, and contexts. Inclusion is not equal endorsement. Each chapter distinguishes evidence-supported components, plausible clinical traditions, contested claims, and practices requiring caution or specialist training.

## How should I choose a theory for a case?

Begin with the young person's goals, presenting pattern, development, culture, family and school contexts, risk, previous responses, and preferences. Identify mechanisms to change, select interventions with evidence and within competence, sequence them, explain the plan, and monitor outcomes. Do not begin by asking which school you personally prefer.

## What if theories conflict?

They often do. Use formulation to decide which level is most relevant now. For example, stabilisation may precede exposure; family accommodation may need to change while individual skills develop; cultural or institutional advocacy may be more urgent than intrapsychic work. Integration must be coherent and explainable.

## Can I use worksheets with real clients?

Templates require local adaptation, consent, safeguarding review, accessibility checks, and professional judgement. Some are teaching forms, not clinical records. Never place identifiable client information into

unsecured systems or external AI tools.

## How much should parents be told?

Parents need enough information to support safety, attendance, and agreed home or school actions. Adolescents also need a confidential therapeutic space. Explain at the outset what categories of information may be shared, obtain views where possible, follow law and safeguarding duties, and record agreements. Avoid verbatim reporting of ordinary session disclosures.

## What should I do when a young person does not want counselling?

Explore what referral means to them, what choices exist, what they fear, and whether attendance is mandated. Distinguish legal or safety requirements from negotiable goals. Motivational interviewing, practical changes, family work, school consultation, or a pause with a clear route back may be more ethical than forcing exploratory therapy.

## Is a diagnosis necessary?

Sometimes diagnosis guides treatment, eligibility, communication, and research. It is rarely sufficient for planning. Formulation adds development, relationships, culture, environment, strengths, mechanisms, and client meaning. Avoid diagnosing from brief vignettes or screening scores.

## How do I handle personal reactions to clients?

Notice them, do not automatically act on them, and use supervision. Emotional responses can reveal relational patterns, practitioner history, team pressure, fatigue, or bias. Record actions and decisions, not speculative claims about a young person's motives.

## What if I suspect abuse or exploitation?

Follow local safeguarding law and organisational procedure immediately. Counselling confidentiality does not override child protection duties. Tell the young person what will happen where safe, record accurately, avoid investigative questioning beyond your role, and seek designated safeguarding advice.

## How should culture be discussed?

Ask respectfully and specifically. Do not demand that a young person educate you about an entire group. Use cultural formulation, interpreters where needed, community resources chosen by the family, and self-reflection on practitioner power. Avoid stereotyping from this book's examples.

## Does affirmative LGBTQ+ practice mean agreeing with every request?

It means not pathologising identity, protecting safety and confidentiality, using chosen language, reducing stigma-related harm, and supporting informed exploration. Clinical, medical, safeguarding, and legal decisions still require individual assessment and local pathways.

## Why is there no faith-based content?

The course specification for this textbook requires professional counselling content without faith-related structures. Culturally responsive counsellors may still need to recognise when clients identify personal beliefs as important, but counsellors should not import religious teaching, ritual, or authority into this secular course framework.

### How should assessment scores be used?

As one source of evidence. Consider validity, norms, language, measurement error, functioning, context, and the young person's account. Scores can support screening, monitoring, and review; they cannot by themselves explain a life or determine worth.

### What makes a good reflective assignment?

Specific observation, separation of fact and inference, accurate theory, cultural and ethical analysis, recognition of uncertainty, and a concrete practice change. Personal disclosure is not the criterion.

### What should I read next after CAC. 701?

Follow the annotated pathways at the end of relevant chapters. Prioritise supervised practice, youth-specific evidence, developmental science, safeguarding, cultural humility, and outcome evaluation over collecting additional brand-name techniques.

## I3. Quick Course Navigation

- **Foundations:** Chapters 1–9
- **Humanistic and experiential:** Chapters 10–15
- **Cognitive and third-wave:** Chapters 16–22
- **Behavioural:** Chapters 23–29
- **Family and relational:** Chapters 30–36
- **Emotion, trauma, and interpersonal:** Chapters 37–43
- **Developmental, social, cultural:** Chapters 44–50
- **Integration and professional practice:** Chapters 51–58
- **Forms and worksheets:** Appendices A, F, G, H
- **Cases:** Appendix B
- **Comparisons and glossary:** Appendices C, D, I
- **Reading pathways:** Appendix E and chapter bibliographies

## Additional Student Questions

### How long should a formulation be?

Long enough to guide decisions and short enough to use. A one-page working formulation with linked mechanisms, strengths, risks, interventions, responsibilities, and review evidence is usually more useful

than a long biography.

## Should I tell a client my theoretical orientation?

Explain your approach in ordinary language when it affects what will happen, what is expected, and what choices exist. Technical labels are optional; informed participation is not.

## What if a technique works but I do not know why?

Monitor outcome and safety, consider common factors and context, discuss in supervision, and avoid claiming a mechanism the evidence does not support.

## What if parents ask for behaviour control?

Explore safety and family strain, explain developmental and ethical limits, assess function, and negotiate goals centred on wellbeing, relationships, learning, and participation rather than obedience alone.

## Can I combine counselling with advocacy?

Yes, where role and consent permit. Advocacy may address interpreters, disability access, bullying, housing, school adjustments, or service coordination. Record the young person's wishes and information-sharing basis.

## How do I know when to refer?

Refer when need exceeds competence, setting, or available intensity; when specialist assessment is required; when risk cannot be managed; or when another service is better matched. Continue appropriate support during transition.

## What should I do after a poor session?

Review promptly, consider rupture and practitioner contribution, check risk or follow-up needs, consult supervision, and plan repair. Do not wait passively for the next scheduled contact if safety or alliance requires action.

## How can I avoid cultural stereotyping?

Ask the individual and family, examine institutional context, use interpreters properly, and treat cultural knowledge as hypotheses to check rather than traits to assign.

## Are practice activities actual therapy?

No. Course role plays and worksheets are educational simulations. Real clinical use requires assessment, consent, competence, supervision, and adaptation.

## What is the most important habit to take from CAC. 701?

Keep returning to formulation: what is happening, for whom, in which contexts, maintained by what, protected by what, and what change would matter enough to test and review?

# I4. How to Study CAC. 701

Theory is learned through contrast, application, and revision. Reading a chapter once produces familiarity, not clinical judgement. A stronger study cycle has seven movements.

First, read the chapter overview and learning objectives before the detailed sections. Predict what the theory will say about a young person's difficulty. This prediction matters because it exposes the assumptions you bring from earlier training, family experience, school experience, or popular psychology.

Second, identify the theory's unit of analysis. Is the practitioner primarily watching behaviour, thought, emotion, relationship, family sequence, story, body state, culture, development, or institutions? Many disagreements between schools are disagreements about where to look first.

Third, translate every major concept into an observable clinical moment. If a term cannot be connected to something a young person says, does, avoids, feels, or experiences from adults, it has not yet become usable knowledge.

Fourth, construct two formulations of the same fictional case: one using the chapter's model and one using a contrasting model. State what each notices, what each misses, what each would do first, and what evidence would change your mind.

Fifth, practise one small skill in a fictional laboratory. Do not attempt to perform an entire therapy. Practise a contract, a reflection, a functional question, a scaling question, a family opening, a grounding invitation, or a repair statement. Small skills reveal assumptions quickly.

Sixth, interrogate development, culture, evidence, and power. Would this work with a younger child, an autistic adolescent, a young carer, a student learning the language of instruction, a young person in care, or a family facing material insecurity? What adaptation is required, and who should make it?

Seventh, write a short review after a delay. Retrieval after several days exposes what was merely recognised during reading. Use the chapter review questions without looking at the text, then return to correct and extend your answers.

## Reading primary sources

Primary texts matter because later summaries often flatten controversy. When reading a founder or major theorist, ask when the work was written, what clinical population it addressed, what methods were available, which claims were empirical, and which were philosophical. Historical importance does not settle present effectiveness.

Pair every classic with a contemporary review. Pair every outcome trial with an implementation question. Pair every manual with a cultural or developmental critique. This triangular reading habit prevents both uncritical adoption and fashionable dismissal.

## Preparing a case presentation

A strong presentation begins with the young person's own words, then context, then pattern, then formulation. It does not begin with a diagnostic label followed by evidence selected to support it. Include what you do not know. State who provided each piece of information. Identify whether family, school, and the young person agree about the problem.

End with a decision: What will be attempted first? What will not be attempted yet? Who else must act? What outcome and date will test the plan? What ethical issue requires supervision? A case presentation without a decision is a story; a case presentation with an unjustified decision is a risk.

## Working in a study group

Assign roles. One student summarises the theory, one challenges its evidence, one examines adolescent adaptation, one examines culture and power, and one converts the discussion into a treatment plan. Rotate roles across weeks so that critique does not become one person's identity and advocacy does not become uncritical loyalty.

Use fictional or fully anonymised material. Do not bring identifiable client details into peer study spaces. If a case resembles your own life or a current client too closely, step back and use supervision or personal support through appropriate channels.

## Preparing for assessment

Examiners reward comparison, application, and justification. When revising, create one-page maps for each theory: person, problem, change, counsellor role, techniques, development, culture, evidence, limits, and best-fit presentation. Then practise applying two maps to an unseen vignette under time limits.

Avoid memorising quotations detached from use. A smaller number of accurately understood concepts will outperform a large vocabulary used decoratively. In skills assessment, markers look for contracting, listening, pacing, safety, responsiveness, and reflection, not theatrical breakthroughs.

## A final professional habit

After every chapter, write one sentence beginning: “Because of this theory, I will now notice…” and one sentence beginning: “Because of its limits, I will be careful not to…” Keep those sentences. Across fifty-eight chapters they become a personal practice philosophy—specific enough to guide behaviour and humble enough to revise.

Boundary . . 193, 284, 357, 358, 359, 360, 362, 364, 365, 369, 371, 382, 388, 522, 524, 750, 753, 837, 852, 854, 855, 857, 859, 860, 861, 863, 864, 865, 866, 870, 996, 1158, 1205, 1326, 1331, 1341
Bowen family systems theory 165, 820, 821, 822, 823, 824, 826, 828, 829, 831, 832, 835, 841, 845, 849, 850, 856, 1352, 1441, 1461
Brain development . . . . . 1202, 1203, 1209
Bronfenbrenner . . . . . 142, 146, 1257, 1260, 1263, 1434
Bulimia . . . . . 864, 1121
Bullying . 683, 995, 1128, 1205, 1232, 1234, 1244, 1245, 1247, 1248, 1261, 1262, 1274, 1287, 1289, 1301, 1325, 1328, 1329, 1339, 1341, 1342, 1395, 1474, 1480

## C

Caregiver . . . . .
Case conceptualization . . . . . 106, 161, 162, 453, 747, 1257, 1286, 1365
Case formulation in behavior therapy . . . . . 642, 645, 646, 656, 661, 685
Case formulation model . . . . . 1292, 1366, 1391, 1398
Case formulation models . . . . .
Change point . . . . . 913, 1019, 1022, 1023, 1025, 1026, 1028, 1029, 1030, 1031, 1034, 1037
Change talk . . . . . 1175, 1178, 1179, 1182

Child and family trauma . . . . . 1049
Co-regulation . . . . . 1112, 1158, 1164, 1204, 1206, 1275
Coaching . . . . . 560, 564, 572, 680, 683, 966, 992, 1019, 1024, 1025, 1027, 1029, 1034, 1037, 1102, 1112, 1180, 1261, 1277, 1399
Coaching and mentoring . . . . . 1247, 1261, 1314, 1339, 1468
Cognitive conceptualization . . . . . 463
Cognitive defusion . . . . . 167, 537, 539, 540, 541, 543, 545, 546, 547, 548, 550, 552
Cognitive processing therapy . . . . . 168
Cognitive therapy . . . . . 94, 139, 162, 167, 182, 205, 276, 446, 447, 448, 451, 452, 453, 454, 455, 457, 461, 463, 470, 471, 472, 475, 479, 515, 516, 523, 528, 551, 552, 581, 583, 585, 588, 590, 594, 688, 738, 743, 746, 747, 749, 753, 755, 1019, 1029, 1056, 1432
Cognitive triad . . . . . 449, 461, 738
Common factors 91, 93, 95, 100, 106, 164, 166, 187, 189, 204, 205, 206, 207, 208, 209, 210, 211, 213, 214, 215, 216, 218, 220, 232, 317, 463, 624, 966, 1278, 1352, 1431, 1480
Communication theory . . . . . 880, 881, 887, 899, 966
Community resources . . . . . 1206, 1262, 1288, 1448, 1474, 1478
Competence . . . . . 13, 92, 103, 113, 118, 120, 122, 123, 124, 126, 181, 189, 205, 230, 238, 257, 263, 286, 287, 289, 290, 456, 457, 478, 482, 737, 743, 750, 755, 837, 867, 973, 1125, 1158, 1179, 1180, 1192, 1231, 1234, 1235, 1246, 1261, 1273, 1274, 1275, 1279, 1288, 1293, 1303, 1305, 1313, 1316, 1318, 1331, 1339, 1344, 1356, 1357, 1367, 1371, 1393, 1405, 1435, 1457, 1458, 1459, 1460, 1461, 1462, 1463, 1464, 1465, 1467, 1472, 1477, 1480
Complex trauma . . . . . 1046, 1048
Conduct disorder . . . . . 205, 262, 263, 623, 718, 864, 918
Confidentiality . . . . . 106, 126, 128, 135, 193, 195, 196, 199, 212, 245, 263, 271, 276, 292, 298, 306, 356, 373, 385, 417, 439, 445, 446, 447, 510, 512, 524, 570, 574, 576, 590, 604, 614, 616, 617, 634, 636, 647, 660, 766, 767, 771, 773, 778, 779, 783, 784, 813, 816, 833, 847, 848, 855, 856, 857, 860, 861, 907, 917, 918, 919, 921, 928, 930, 931, 940, 964, 965, 967, 1013, 1015, 1019, 1040, 1046, 1047, 1049, 1091, 1114, 1116, 1117, 1152, 1154, 1160, 1161, 1162, 1197, 1211, 1212, 1225, 1226, 1232, 1235, 1239, 1240, 1250, 1251, 1263, 1265, 1267, 1268, 1270, 1281, 1287, 1288, 1289, 1290, 1291, 1292, 1293, 1294, 1295, 1296, 1297, 1298, 1299, 1300, 1301, 1302, 1303, 1304, 1305, 1306, 1307, 1308, 1309, 1310, 1311, 1312, 1313, 1314, 1315, 1316, 1317, 1318, 1319, 1320, 1321, 1322, 1323, 1324, 1325, 1326,

Cultural identity . . . . . 250, 251, 254, 263, 264, 1258

## D

Decentering . . . . . 581, 583, 584, 585, 590, 594

Decision-making in counseling . . . . . 93, 292, 341, 498, 548, 860, 920, 1134, 1202, 1231, 1234, 1235

Depression . . . . . 65, 68, 165, 167, 192, 269, 286, 289, 311, 220, 232, 236, 237, 276, 281, 284, 539, 540, 542, 543, 584, 671, 672, 691, 694, 695, 697, 661, 665, 670, 673, 674, 675, 677, 679, 684, 686, 697, 800, 802, 804, 816, 821, 825, 838, 844, 846, 861, 865, 867, 868, 890, 890, 892, 894, 618, 625, 666, 737, 738, 739, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 752, 795, 796, 794, 802, 816, 910, 975, 976, 981, 1020, 1021, 1120, 1121, 1125, 1126, 1128, 1129, 1130, 1132, 1135, 1141, 1142, 1146, 1148, 1221, 1245, 1256, 1305, 1320, 1329, 1360, 1395, 1397, 1398, 1435, 1447

Dialectical behavior therapy . . . . . 140, 141, 559, 560, 566, 568

Differential reinforcement . . . . . 611, 622, 624, 625, 705, 726, 730, 768, 797, 800, 801

Differentiation of self . . . . 165, 359, 360, 362, 365, 369, 430, 459, 613, 820, 824, 825, 826, 828, 832, 833, 834, 835, 837, 841, 845, 853, 860, 866, 912, 1052

Dissociation . . . 108, 131, 154, 168, 175, 199, 222, 245, 271, 299, 326, 350, 360, 361, 373, 384, 395, 401, 417, 423, 426, 439, 465, 488, 510, 532, 554, 576, 598, 637, 667, 700, 732, 758, 785, 813, 847, 875, 902, 930, 960, 986, 1012, 1020, 1027, 1039, 1046, 1052, 1066, 1090, 1103, 1104, 1115, 1131, 1136, 1153, 1158, 1161, 1164, 1168, 1184, 1197, 1211, 1218, 1225, 1239, 1252, 1266, 1281, 1294, 1307, 1320, 1326, 1333, 1346, 1359, 1373

Distress tolerance . . . . . 559, 567, 572, 1100

Documentation standards . . . -12, -5, 342, 560, 564, 570, 624, 635, 730, 790, 793, 803, 1044, 1056, 1060, 1102, 1107, 1279, 1292, 1293, 1305, 1318, 1331, 1344, 1357, 1371, 1388, 1431

Double bind . . . . . 142, 165, 858, 859, 880, 881, 883, 886, 887, 888, 897, 899

Drama triangle . . . . . 415

Dropout . . . . . 187, 230, 231, 233, 241, 243, 1312, 1315, 1316

Dual systems model . . . . . 1203

## E

Early maladaptive schema . . . . . 515, 516, 517, 520, 521, 528

Eclectic theory . . . . . 94, 1274, 1431

Ecological systems . . . . . 1257, 1258, 1434

Effect size . . . . . -9, -3, 386, 431, 455, 479, 547, 590, 652, 686, 687, 719, 747, 773, 782, 1001, 1029, 1076, 1081, 1366

Effectiveness and efficacy 92, 100, 113, 116, 119, 206, 207, 211, 213, 215, 218, 227, 228, 230, 235, 238, 239, 241, 243, 254, 264, 267, 291, 340, 431, 446, 476, 480, 563, 614, 681, 682, 686, 688, 708, 746, 747, 913, 996, 1029, 1071, 1072, 1081, 1082, 1126, 1190, 1191, 1192, 1193, 1195, 1246, 1260, 1326, 1327, 1366, 1433, 1481

Ego state . . . . . 400, 401, 402, 403, 406, 409, 415

EMDR . . . . . 168, 1050, 1055, 1063, 1071, 1072, 1074, 1076, 1077, 1081, 1087, 1088, 1092, 1098, 1101, 1276, 1352, 1434, 1442, 1462, 1477

Emotion regulation in youth . . . . . 937, 954

Emotion regulation skills . . . . . 563, 1100

Emotion-focused therapy . . . . . 138, 281, 1019, 1025, 1029

Emotional cutoff . . . . . 165, 820, 841

Emotional regulation . . . . . 559, 561, 565, 567, 572, 1024, 1025, 1037, 1054, 1202, 1203, 1206, 1275

Empathic attunement . . . . . 138, 168, 311, 316, 426, 549, 1020

Empathy . . . 138, 163, 183, 185, 189, 208, 309, 311, 313, 314, 316, 318, 337, 346, 519, 520, 521, 523, 524, 525, 529, 1020, 1023, 1024, 1141, 1176, 1180, 1217, 1261, 1274, 1328

Empowerment . . . . . 1175, 1176, 1230, 1231, 1235

Empty chair . . . . . 86, 169, 355, 357, 360, 364, 365, 366, 367, 369, 521, 1023

Enactment . . . . . 90, 184, 852, 858, 865, 866, 869, 870, 873, 880, 884, 897, 1120, 1124, 1125, 1216, 1218
Encouragement . . . . . 402, 625, 718, 1124, 1125, 1195, 1220
Epistemic trust . . . . . 1141, 1145, 1151, 1396
Erikson . . . . . 277, 279, 280, 294, 1204, 1205, 1209
Erikson psychosocial stages . . . . . 1204
Ethical standards . . . . . -13, 85, 91, 92, 93, 101, 120, 121, 126, 128, 166, 292, 1299
Ethnic minority . . . . . 257, 1003, 1303
Evidence hierarchy . . . . . 227, 229, 241
Evidence-based practice . . . . . 167, 228, 235, 238, 239, 243, 264, 341, 446, 1408
Exception . . . . . 90, 715, 742, 965, 966, 967, 968, 972, 973, 974, 976, 977, 978, 980, 981, 984, 991, 1316
Executive function . . . . . 279, 471
Existential therapy . . . . . 138, 331, 333, 337, 338, 339, 340, 346, 348
Expectancy effect . . . . . 386, 1081
Exposure therapy 86, 138, 141, 162, 169, 210, 211, 212, 237, 252, 277, 290, 363, 388, 455, 476, 478, 479, 480, 494, 503, 521, 538, 544, 562, 606, 610, 611, 612, 615, 618, 620, 623, 630, 672, 673, 674, 675, 676, 677, 678, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 693, 694, 697, 698, 717, 718, 738, 739, 744, 885, 1021, 1078, 1206, 1248, 1274, 1275, 1276, 1289, 1290, 1301, 1326, 1352, 1393, 1396, 1397, 1450, 1477
Externalization . . . . . 260, 432, 991, 992, 993, 995, 998, 999, 1000, 1006, 1010, 1274, 1275
Extinction . . . . . 163, 605, 606, 610, 611, 615, 630, 705, 709, 710, 713, 729, 791, 794, 797, 800, 807
Eye movements . . . . . 1071, 1072, 1073, 1075

Gestalt therapy . . . . 138, 355, 356, 357, 358, 362, 363, 364, 365, 367, 369, 371, 376, 387, 391, 1352, 1431, 1438, 1459
Goal setting . . . . . 186, 1291
Grief and loss . -12, 176, 337, 342, 344, 374, 517, 544, 546, 555, 913, 940, 943, 1019, 1021, 1026, 1028, 1029, 1030, 1031, 1034, 1049, 1072, 1077, 1078, 1121, 1122, 1126, 1127, 1128, 1130, 1131, 1132, 1146, 1234, 1247, 1258, 1259, 1295, 1312, 1314, 1340, 1396, 1401, 1433, 1468, 1473
Grounding . . . . . 169, 356, 388, 393, 477, 592, 1047, 1048, 1054, 1055, 1061, 1095, 1096, 1097, 1098, 1099, 1100, 1102, 1103, 1104, 1105, 1106, 1107, 1110, 1112, 1145, 1146, 1158, 1273, 1275, 1276, 1329, 1354, 1450, 1481

## H

Here and now . . . . . 355, 357, 358, 359, 362, 363, 364, 366, 367, 369, 406, 407, 409, 410, 411, 540, 1097, 1162
Herman . . . . . 168, 1433, 1434
Hexaflex . . . . . 537, 540, 550, 552
Homework . . . . . 185, 189, 209, 220, 289, 319, 451, 494, 498, 499, 501, 502, 503, 520, 563, 564, 567, 621, 624, 673, 677, 678, 679, 680, 681, 682, 694, 697, 742, 764, 862, 863, 916, 917, 1125, 1163, 1206, 1326, 1342, 1383, 1392, 1394
Humanistic methods . . . . . -13, -10, 87, 88, 99, 103, 113, 115, 116, 117, 126, 136, 137, 138, 145, 146, 147, 149, 151, 152, 159, 161, 163, 169, 171, 182, 185, 195, 204, 205, 208, 213, 232, 259, 357, 363, 379, 380, 387, 391, 407, 503, 549, 607, 609, 651, 662, 821, 1352
Hypothesis testing . . . . . 210, 647

## I

Identity development . . . . . 256, 257, 258, 264, 1244, 1245
Implementation science . 227, 228, 230, 235, 238, 241, 566, 568, 569, 574, 653, 719, 720, 763, 766, 771, 772, 773, 774, 779, 782, 1148, 1150, 1305, 1344, 1431, 1436, 1437, 1438, 1439, 1440, 1441, 1442, 1443, 1444, 1445, 1481
In vivo exposure . . . . . 672, 673, 675, 693
Informed consent . . . . . 92, 103, 120, 122, 886, 893, 897, 981, 1303
Insight 101, 142, 163, 165, 241, 260, 265, 287, 291, 334, 378, 401, 474, 559, 624, 644, 672, 686, 705, 892, 899, 965, 972, 977, 1047, 1124, 1141, 1159, 1175, 1219, 1235, 1275, 1396
Integrative formulation . . . . . 1276
Integrative framework . . . . . 89
Intermediate beliefs . . . . . 448, 449, 458, 461
Internal Family Systems . . . . . 422, 428, 431, 1352
Interpersonal effectiveness . . . . . 559, 565, 572
Interpersonal psychotherapy . . . . . 1120, 1121, 1122, 1125
Interpreter . . . . 894, 938, 1121, 1231, 1232, 1234, 1235, 1237, 1261, 1300, 1329, 1342, 1378, 1380, 1392, 1400, 1472, 1478, 1480
Intersectionality . . . . . 171, 252, 267, 1230, 1237, 1435
Involuntary treatment . . . . . 606

## K

Klerman . . . . . 1120, 1125, 1133, 1433
Kohlberg . . . . . 285, 286

## L

Legal mandates . . . . . 115, 867, 870, 1177, 1453
LGBTQ+ affirmation . 193, 335, 1130, 1131, 1231, 1232, 1233, 1244, 1245, 1246, 1248, 1250, 1254, 1255, 1339, 1352, 1435, 1444, 1464, 1468
Linehan . . . . . 167, 173, 559, 560, 561, 566, 572, 574, 937, 944, 1100, 1112, 1432

## M

Maintenance and generalization . . . . . 85, 86, 96, 120, 164, 403, 449, 454, 455, 474, 479, 522, 526, 582, 615, 675, 710, 712, 748, 749, 753, 832, 852, 862, 865, 870, 937, 954, 1046, 1113, 1287
Mandatory disclosure . . . . . 197, 626, 838, 1050, 1057, 1061
Manualized treatment . . . . . 116, 209, 243, 486, 681, 739, 1125, 1431
Manuals and flexibility . . . . . 85, 86, 88, 146, 185, 279, 508, 539, 544, 584, 591, 596, 611, 1355, 1395, 1400
Masten . . . . . 1258, 1260, 1263, 1264, 1434
Meaning . . . . . 15, 40, 47, 104, 126, 176, 177, 178, 181, 183, 184, 185, 189, 196, 227, 228, 236, 239, 245, 247, 260, 261, 274, 294, 310, 320, 327, 330, 332, 333, 334, 356, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 374, 376, 396, 404, 416, 419, 446, 451, 459, 463, 464, 468, 470, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 1350, 1351, 1352, 1353, 1354, 1355, 1356, 1357, 1358, 1359, 1360, 1361, 1362, 1363, 1364, 1365, 1366, 1367, 1368, 1369, 1370, 1371, 1372, 1373, 1374, 1375, 1376, 1377, 1378, 1379, 1380, 1381, 1382, 1383, 1384, 1385, 1386, 1387, 1388, 1389, 1390, 1391, 1392, 1393, 1394, 1395, 1396, 1397, 1398, 1399, 1400, 1401, 1402, 1403, 1404, 1405, 1406, 1407, 1408, 1409, 1410, 1411, 1412, 1413, 1414, 1415, 1416, 1417, 1418, 1419, 1420, 1421, 1422, 1423, 1424, 1425, 1426, 1427, 1428, 1429, 1430, 1431, 1432, 1433, 1434, 1435, 1436, 1437, 1438, 1439, 1440, 1441, 1442, 1443, 1444, 1445, 1446, 1447, 1448, 1449, 1450, 1451, 1452, 1453, 1454, 1455, 1456, 1457, 1458, 1459, 1460, 1461, 1462, 1463, 1464, 1465, 1466, 1467, 1468, 1469, 1470, 1471, 1472, 1473, 1474, 1475, 1476, 1477, 1478, 1479, 1480, 1481, 1482, 1483, 1484, 1485, 1486, 1487, 1488, 1489
Mechanism of change . . . . . -13, -10, -8, -6, 86, 94, 96, 147, 149, 164, 322, 407, 410, 426, 583, 737, 1180, 1292
Mentalization 424, 937, 949, 1052, 1056, 1141, 1142, 1143, 1144, 1145, 1146, 1147, 1148, 1151, 1218, 1221, 1223, 1352, 1394, 1401
Meta-analysis . . . . . 119, 128, 197, 227, 229, 233, 477, 588, 596, 682, 1076, 1087
Metacognition . . . . . 278, 596
Microaggression . . . . . 253
Miller and Rollnick . . . . . 1177, 1182
Mindfulness 160, 238, 385, 559, 562, 563, 572, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 596, 607, 997, 1098, 1352
Mindfulness-based cognitive therapy . . . . . 140, 167, 581, 582, 590, 591
Mindfulness-based stress reduction . . . . . 167, 581, 582
Minority stress . . . . . 168, 263, 264, 267, 269, 1244
Minuchin . . . . . 165, 173, 821, 852, 853, 854, 855, 859, 869, 872, 873, 1433
Miracle question . . . . . 169, 186, 965, 968, 969, 972, 974, 978, 981
Model of the person . . . . . 96, 146, 400
Modeling . 164, 455, 472, 476, 479, 608, 615, 672, 673, 679, 681, 682, 684, 712, 910, 970, 1189, 1190, 1192, 1193, 1194, 1195, 1432
Modeling and observation . . . . . 620, 1189, 1190
Moral reasoning . . . . . 285, 286, 291, 508, 564
Motivation . . . . . -13, 109, 116, 131, 154, 163, 176, 200, 215, 223, 246, 272, 279, 281, 283, 287, 299, 311, 327, 336, 339, 351, 374, 396, 418, 440, 450, 466, 511, 533, 555, 577, 599, 678, 681, 689, 709, 719, 749, 880, 888, 892, 1025, 1090, 1115, 1153, 1175, 1178, 1180, 1182, 1190, 1196, 1198, 1209, 1223, 1237, 1250, 1264, 1266, 1281, 1295, 1357, 1473
Motivation in therapy . . . . . 285, 337, 338, 607, 1050, 1101, 1102, 1278
Motivational interviewing . . . . . 86, 138, 966, 971, 1175, 1276, 1339, 1352, 1393
Multicultural competence . . . . . 251, 267, 269, 912
Multicultural theory . . . . . 168, 250, 258, 269, 1230, 1435
Multidisciplinary team . . . . . 12, 86, 122, 151, 162, 167, 214, 223, 230, 231, 262, 307, 327, 378, 379, 391, 418, 511, 516, 559, 560, 564, 569, 572, 599, 624, 656, 657, 684, 686, 713, 720, 744, 746, 764, 768, 769, 771, 773, 774, 775, 782, 792, 799, 800, 802, 803, 804, 808, 831, 837, 880, 881, 886, 893, 897, 899, 943, 947, 948, 950, 965, 1145, 1146, 1148, 1153, 1258, 1266, 1305, 1330, 1369, 1394, 1399, 1454, 1478

Multisystemic therapy . . . . . 845, 865, 870, 873, 928
Multitiered systems of support . . . . . 1338, 1339

## N

Narrative therapy . . . . . 899, 991, 995, 996, 997, 1001
National origin . . . . . 120, 264
Negative reinforcement . . . . . 605, 613, 614, 647, 711
Negative reinforcement and escape . . . . . 621, 656, 684, 712, 713, 714, 726, 730, 791, 796, 797, 802, 807, 925
Neuroception . . . . . 1166
Neurodevelopment of the adolescent brain . . . . . 276, 282, 283, 291, 296, 586, 1045, 1434
Nuanced technique
Nuclear family emotional process . . . . . 165, 820, 841, 845

## O

Object relations . . . . . 1216, 1218
Oppositional behavior . . . . . 94, 123, 408, 623, 630, 651, 707, 714, 718, 719, 726, 730, 862, 863, 864, 870, 889, 909, 918, 1053, 1128, 1202, 1206, 1234

## P

Parent management training . . . . . 913
Parental consent . . . . . 430, 1164
Parts system . . . . . -13, -4, 117, 142, 180, 355, 356, 357, 411, 422, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 435, 437, 537, 697, 796, 826, 882, 908, 992, 998, 999, 1000, 1279, 1288, 1293, 1305, 1318, 1331, 1344, 1352, 1357, 1371
Passivity . . . . . 540
Peer relations . . . . . 269, 280, 286, 482, 587, 594, 625, 776, 779, 854, 894, 1123, 1209, 1247, 1258, 1314
Peer support . . . . . 168, 1044, 1045, 1449
Perls . . . . . 355, 357, 363, 369, 371, 1431
Perpetuating factors . . . . . 98, 1275, 1286, 1288, 1290
Person-centered theory . . . . . 314
Phased treatment . . . . . 1051
Piaget . . . . . 277, 278, 279, 294, 1026
Placebo . . . . . 95, 106, 163, 204, 206, 207, 208, 210, 215, 218, 220, 623, 1121
Placebo and specific effects . . . . . 204, 206, 209, 211, 213, 218
Pleasure mastery . . . . . 339, 738, 741, 744, 1175, 1177, 1449
Polyvagal theory . . . . . 1049, 1063, 1158, 1165, 1434
Polyvagal-informed . . . . . 168, 1158, 1434

Positive punishment . . . . . 614
Post-termination . . . . . 1318
Post-traumatic stress . . . . . 100, 114, 452, 504, 674, 681, 686, 1071, 1072, 1081, 1100, 1103, 1112, 1121
Postmodern . . . . . 144
Poverty and counseling 111, 133, 156, 163, 168, 170, 202, 225, 230, 248, 252, 254, 274, 285, 292, 301, 316, 329, 353, 376, 390, 420, 442, 457, 468, 491, 513, 535, 557, 579, 601, 640, 670, 703, 735, 760, 787, 816, 822, 850, 854, 878, 904, 920, 932, 958, 963, 971, 972, 980, 1014, 1042, 1068, 1092, 1117, 1131, 1138, 1155, 1170, 1187, 1190, 1200, 1202, 1213, 1228, 1242, 1255, 1258, 1259, 1268, 1283, 1291, 1297, 1310, 1322, 1336, 1348, 1362, 1376, 1400
Power and privilege
Practice-based evidence . . . . . -12, 91, 227, 231, 624, 630, 966
Precipitating factors . . . . . 1275, 1286
Predisposing factors . . . . . 1275, 1286
Prefrontal cortex . . . . . 168, 282, 291
Proactive classroom management . . . . . 424, 1097
Problem-maintaining sequence . . . . . 880, 882, 888, 892, 896, 900
Professional identity . . . . . 84, 92, 101, 126, 129, 166
Program curriculum . . . . . 118, 120, 189, 291, 311, 607, 838, 927, 1134, 1180, 1206, 1247, 1261, 1341, 1432, 1472
Prolonged exposure . . . . . 168
Protective factor . . 123, 254, 263, 267, 566, 743, 795, 916, 1046, 1126, 1245, 1258, 1264, 1290, 1301, 1302, 1453, 1472
Protective factors
Psychodynamic theory . . . . . 87, 95, 116, 145, 161, 162, 184, 191, 192, 195, 204, 205, 206, 260, 307, 322, 333, 336, 401, 458, 519, 530, 1125, 1216, 1217, 1218, 1219, 1221, 1222, 1223, 1274, 1352
Psychological flexibility . . . . . 167, 537, 546, 550, 552, 1432
Puberty . . . . . 283, 938, 1162, 1202, 1207, 1467

## R

Randomized controlled trial . . . -12, 116, 119, 229, 422, 431, 455, 475, 479, 523, 546, 581, 948, 1076, 1081, 1121, 1145
Re-authoring . . . . . 991, 994, 995, 996, 998, 999, 1000, 1002, 1003, 1006, 1007, 1432
Reciprocal determinism . . . . . 1189, 1195
Reciprocity . . . . . 208, 681, 716, 726, 1205
Referral
Reflective functioning . . . . . 424, 427, 1141, 1142, 1150
Reflective listening . . . . . 1175, 1180
Reinforcement . . . 86, 93, 97, 140, 160, 164, 182, 259, 464, 486, 509, 518, 531, 553, 563, 575, 597, 608, 609, 613, 614, 615, 616, 618, 619, 625, 630, 644, 647, 656, 657, 686, 694, 705, 707, 708, 709, 710, 711, 713, 714, 718, 719, 720, 721, 725, 726, 729, 730, 742, 764, 765, 767, 774, 775, 779, 783, 797, 800, 801, 909, 910, 914, 1275, 1287, 1400, 1447
Reinforcement history . . . . . 616
Relapse 108, 131, 154, 167, 170, 200, 223, 246, 272, 299, 327, 351, 374, 396, 418, 440, 466, 474, 488, 498, 511, 533, 555, 577, 581, 582, 585, 590, 591, 594, 596, 637, 667, 675, 687, 700, 718, 732, 748, 749, 753, 758, 785, 813, 847, 864, 875, 902, 930, 960, 986, 1012, 1039, 1066, 1090, 1115, 1120, 1120, 1136, 1153, 1168, 1184, 1198, 1211, 1225, 1239, 1252, 1266, 1281, 1295, 1307, 1313, 1314, 1316, 1320, 1333, 1346, 1359, 1373
Relapse prevention . 464, 466, 486, 503, 509, 511, 530, 533, 553, 555, 575, 577, 582, 585, 586, 587, 588, 591, 594, 596, 597, 599, 749, 1128, 1312, 1318, 1432
Reliability . . . . . 184, 210, 314, 471, 516, 522, 523, 607, 617, 681, 831, 836, 948, 1051, 1126, 1145, 1299, 1383
Resilience 216, 254, 261, 263, 269, 340, 966, 1049, 1182, 1196, 1209, 1223, 1237, 1249, 1250, 1257, 1259, 1260, 1261, 1262, 1264, 1352, 1392, 1395, 1434, 1455

Risk assessment . . . . . 338, 342, 346, 560, 566, 574, 655, 793, 795, 807, 978, 1394, 1397, 1450
Risk factor . . . . . 1258
Risk-taking . . . . . 276, 282, 283, 291, 908
Role play . . . . . 910, 1124, 1351, 1353, 1480
Role transition . . . . . 1122, 1126, 1127, 1128
Rubric . . . . . -10, -9, -6, -5, 1364, 1371
Rupture 180, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 195, 197, 213, 342, 830, 942, 943, 945, 946, 1021, 1126, 1216, 1276, 1302, 1453, 1454, 1455, 1480

## S

Safety planning . 343, 560, 564, 566, 569, 570, 572, 792, 793, 795, 799, 807, 1053, 1054, 1107, 1112, 1382, 1385, 1468, 1469, 1470
Scaling . . . . . 965, 971, 974, 1276, 1481
Schedules of reinforcement . . . . . 618, 705
Schema . . . . 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 528, 529, 530, 540, 582, 938, 939, 1352, 1432
Schema therapy . . . . . 140, 515, 516, 520, 521, 522, 523, 568
School counseling . -13, -3, 84, 114, 117, 154, 162, 246, 351, 440, 533, 683, 822, 966, 971, 1090, 1281, 1338, 1344, 1434
School refusal . . . . . -12, 236, 237, 272, 466, 478, 525, 675, 679, 683, 684, 687, 698, 832, 838, 888, 1115, 1315, 1365
Scope of practice . . . . . 120, 124
Script . . . . . 400, 401, 403, 404, 405, 406, 407, 408, 409, 410, 411, 413, 415, 679, 768, 1097, 1124, 1128, 1129, 1351
Secure base . . . . . 281, 518, 522, 525, 908, 937, 943, 945, 946, 951, 954, 1076, 1077, 1079
Selective mutism . . . . . 1234
Self-disclosure . . . . . 260
Self-efficacy . . . . . 164, 212, 608, 1124, 1189, 1195
Self-harm . . . . . 15, 106, 170, 194, 197, 198, 200, 223, 224, 272, 299, 329, 527, 559, 562, 564, 581, 575, 596, 617, 671, 679, 684, 688, 690, 830, 833, 835, 836, 852, 854, 858, 860, 864, 865, 866, 867, 868, 869, 870, 874, 876, 899, 924, 937, 940, 945, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000, 1001, 1002, 1003, 1004, 1005, 1006, 1007, 1008, 1009, 1010, 1011, 1012, 1013, 1014, 1015, 1016, 1017, 1018, 1019, 1020, 1021, 1022, 1023, 1024, 1025, 1026, 1027, 1028, 1029, 1030, 1031, 1032, 1033, 1034, 1035, 1036, 1037, 1038, 1039, 1040, 1041, 1042, 1043, 1044, 1045, 1046, 1047, 1048, 1049, 1050, 1051, 1052, 1053, 1054, 1055, 1056, 1057, 1058, 1059, 1060, 1061, 1062, 1063, 1064, 1065, 1066, 1067, 1068, 1069, 1070, 1071, 1072, 1073, 1074, 1075, 1076, 1077, 1078, 1079, 1080, 1081, 1082, 1083, 1084, 1085, 1086, 1087, 1088, 1089, 1090, 1091, 1092, 1093, 1094, 1095, 1096, 1097, 1098, 1099, 1100, 1101, 1102, 1103, 1104, 1105, 1106, 1107, 1108, 1109, 1110, 1111, 1112, 1113, 1114, 1115, 1116, 1117, 1118, 1119, 1120, 1121, 1122, 1123, 1124, 1125, 1126, 1127, 1128, 1129, 1130, 1131, 1132, 1133, 1134, 1135, 1136, 1137, 1138, 1139, 1140, 1141, 1142, 1143, 1144, 1145, 1146, 1147, 1148, 1149, 1150, 1151, 1152, 1153, 1154, 1155, 1156, 1157, 1158, 1159, 1160, 1161, 1162, 1163, 1164, 1165, 1166, 1167, 1168, 1169, 1170, 1171, 1172, 1173, 1174, 1175, 1176, 1177, 1178, 1179, 1180, 1181, 1182, 1183, 1184, 1185, 1186, 1187, 1188, 1189, 1190, 1191, 1192, 1193, 1194, 1195, 1196, 1197, 1198, 1199, 1200, 1201, 1202, 1203, 1204, 1205, 1206, 1207, 1208, 1209, 1210, 1211, 1212, 1213, 1214, 1215, 1216, 1217, 1218, 1219, 1220, 1221, 1222, 1223, 1224, 1225, 1226, 1227, 1228, 1229, 1230, 1231, 1232, 1233, 1234, 1235, 1236, 1237, 1238, 1239, 1240, 1241, 1242, 1243, 1244, 1245, 1246, 1247, 1248, 1249, 1250, 1251, 1252, 1253, 1254, 1255, 1256, 1257, 1258, 1259, 1260, 1261, 1262, 1263, 1264, 1265, 1266, 1267, 1268, 1269, 1270, 1271, 1272, 1273, 1274, 1275, 1276, 1277, 1278, 1279, 1280, 1281, 1282, 1283, 1284, 1285, 1286, 1287, 1288, 1289, 1290, 1291, 1292, 1293, 1294, 1295, 1296, 1297, 1298, 1299, 1300, 1301, 1302, 1303, 1304, 1305, 1306, 1307, 1308, 1309, 1310, 1311, 1312, 1313, 1314, 1315, 1316, 1317, 1318, 1319, 1320, 1321, 1322, 1323, 1324, 1325, 1326, 1327, 1328, 1329, 1330, 1331, 1332, 1333, 1334, 1335, 1336, 1337, 1338, 1339, 1340, 1341, 1342, 1343, 1344, 1345, 1346, 1347, 1348, 1349, 1350, 1351, 1352, 1353, 1354, 1355, 1356, 1357, 1358, 1359, 1360, 1361, 1362, 1363, 1364, 1365, 1366, 1367, 1368, 1369, 1370, 1371, 1372, 1373, 1374, 1375, 1376, 1377, 1378, 1379, 1380, 1381, 1382, 1383, 1384, 1385, 1386, 1387, 1388, 1389, 1390, 1391, 1392, 1393, 1394, 1395, 1396, 1397, 1398, 1399, 1400, 1401, 1402, 1403, 1404, 1405, 1406, 1407, 1408, 1409, 1410, 1411, 1412, 1413, 1414, 1415, 1416, 1417, 1418, 1419, 1420, 1421, 1422, 1423, 1424, 1425, 1426, 1427, 1428, 1429, 1430, 1431, 1432, 1433, 1434, 1435, 1436, 1437, 1438, 1439, 1440, 1441, 1442, 1443, 1444, 1445, 1446, 1447, 1448, 1449, 1450, 1451, 1452, 1453, 1454, 1455, 1456, 1457, 1458, 1459, 1460, 1461, 1462, 1463, 1464, 1465, 1466, 1467, 1468, 1469, 1470, 1471, 1472, 1473, 1474, 1475, 1476, 1477, 1478, 1479, 1480, 1481, 1482, 1483, 1484, 1485, 1486, 1487, 1488, 1489, 1490, 1491, 1492
Self-management training . . . . . 680
Self-monitoring . . . . . 433, 1106, 1192
Self-reflection . . . . . 185, 1478
Self-regulation skills . . . . 94, 283, 287, 294, 430, 586, 594, 721, 1096, 1105, 1161, 1189, 1192, 1194, 1258, 1262, 1436
Sensorimotor psychotherapy . . . . . 168, 278, 1100, 1112, 1158, 1165
Sequencing of treatment . . . . . 120, 168, 745, 863, 907, 914, 1274, 1276, 1286, 1408
Session . . . . . 1
Shaping . . . . . 163, 182, 212, 605, 630, 705, 712, 717, 718, 730, 993
Shaping and prompting . . . . 109, 131, 154, 176, 200, 223, 246, 272, 299, 327, 351, 374, 396, 418, 440, 466, 472, 511, 533, 555, 577, 599, 605, 615, 618, 630, 705, 718, 765, 769, 1090, 1099, 1115, 1153, 1198, 1266, 1281, 1295
Shapiro . . . . . 832, 845, 1072, 1076, 1077, 1087, 1434
Single-case design . . . . . -12, 91, 116, 119, 229, 241, 608, 623, 624, 630, 635, 649, 662, 665, 801, 808, 1001
Social determinants . . . . . 139, 261, 341

Social justice . . . . . -13, 143, 146, 171, 267, 317, 365, 997
Social learning in the classroom . . . . . 163
Social learning theory . . . . . 608, 678, 681, 1189
Social media . . . . . 1340
Social skills training . . . . . 287
Solution-focused brief therapy . . . . . 90, 144, 186, 882, 887, 892, 897, 899, 900, 965, 966, 969, 970, 971, 972, 974, 976, 977, 978, 980, 983, 995, 1276, 1339, 1352
Solution-focused practice . . . . . 972, 980
Special education . . . . . 1344
Stabilization . . . . . 107, 129, 143, 166, 174, 198, 233, 244, 259, 297, 324, 340, 360, 372, 384, 393, 395, 396, 410, 423, 427, 428, 432, 433, 434, 435, 436, 438, 439, 440, 446, 448, 449, 450, 451, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000, 1001, 1002, 1003, 1004, 1005, 1006, 1007, 1008, 1009, 1010, 1011, 1012, 1013, 1014, 1015, 1016, 1017, 1018, 1019, 1020, 1021, 1022, 1023, 1024, 1025, 1026, 1027, 1028, 1029, 1030, 1031, 1032, 1033, 1034, 1035, 1036, 1037, 1038, 1039, 1040, 1041, 1042, 1043, 1044, 1045, 1046, 1047, 1048, 1049, 1050, 1051, 1052, 1053, 1054, 1055, 1056, 1057, 1058, 1059, 1060, 1061, 1062, 1063, 1064, 1065, 1066, 1067, 1068, 1069, 1070, 1071, 1072, 1073, 1074, 1075, 1076, 1077, 1078, 1079, 1080, 1081, 1082, 1083, 1084, 1085, 1086, 1087, 1088, 1089, 1090, 1091, 1092, 1093, 1094, 1095, 1096, 1097, 1098, 1099, 1100, 1101, 1102, 1103, 1104, 1105, 1106, 1107, 1108, 1109, 1110, 1111, 1112, 1113, 1114, 1115, 1116, 1117, 1118, 1119, 1120, 1121, 1122, 1123, 1124, 1125, 1126, 1127, 1128, 1129, 1130, 1131, 1132, 1133, 1134, 1135, 1136, 1137, 1138, 1139, 1140, 1141, 1142, 1143, 1144, 1145, 1146, 1147, 1148, 1149, 1150, 1151, 1152, 1153, 1154, 1155, 1156, 1157, 1158, 1159, 1160, 1161, 1162, 1163, 1164, 1165, 1166, 1167, 1168, 1169, 1170, 1171, 1172, 1173, 1174, 1175, 1176, 1177, 1178, 1179, 1180, 1181, 1182, 1183, 1184, 1185, 1186, 1187, 1188, 1189, 1190, 1191, 1192, 1193, 1194, 1195, 1196, 1197, 1198, 1199, 1200, 1201, 1202, 1203, 1204, 1205, 1206, 1207, 1208, 1209, 1210, 1211, 1212, 1213, 1214, 1215, 1216, 1217, 1218, 1219, 1220, 1221, 1222, 1223, 1224, 1225, 1226, 1227, 1228, 1229, 1230, 1231, 1232, 1233, 1234, 1235, 1236, 1237, 1238, 1239, 1240, 1241, 1242, 1243, 1244, 1245, 1246, 1247, 1248, 1249, 1250, 1251, 1252, 1253, 1254, 1255, 1256, 1257, 1258, 1259, 1260, 1261, 1262, 1263, 1264, 1265, 1266, 1267, 1268, 1269, 1270, 1271, 1272, 1273, 1274, 1275, 1276, 1277
Stage of change . . . . . 1278, 1431
Standardization . . . . . 205, 234, 236, 237, 616, 1001, 1076, 1287, 1305
Strengths-based practice . . . . . 138, 241, 642, 768, 842, 870, 897, 925, 966, 967, 971, 973, 981, 1007, 1034, 1050, 1061, 1110, 1145, 1176, 1177, 1179, 1206, 1217, 1219, 1234, 1257, 1259, 1261, 1263, 1274, 1286, 1287, 1299, 1301, 1340, 1392, 1472, 1473, 1474, 1478
Structural dissociation . . . . . 422, 423, 427, 428, 431, 432, 435, 437
Structural family therapy . . . . . 852, 859, 864, 865, 873, 1433
Substance use . . . . . 118, 167, 214, 286, 422, 423, 431, 435, 454, 546, 623, 630, 719, 726, 730, 739, 744, 748, 773, 782, 822, 830, 832, 836, 845, 860, 882, 913, 916, 918, 928, 1126, 1161, 1175, 1180, 1245, 1287, 1301, 1302, 1393
Subsystem . . . . . 165, 820, 823, 828, 833, 834, 835, 842, 852, 854, 855, 856, 857, 858, 859, 860, 861, 863, 864, 865, 866, 867, 870, 873, 907, 924, 1397, 1399
Suicide . . . . . 167, 286, 338, 342, 343, 344, 559, 560, 566, 574, 830, 973, 1130, 1245, 1276, 1340, 1393, 1469
Suicide assessment . . . . . 564, 566, 570
Supervision . . . . . -12, -8, -5, 93, 95, 100, 120, 144, 214, 215, 230, 236, 237, 256, 388, 411, 621, 622, 747, 749, 792, 831, 837, 873, 893, 919, 1003, 1031, 1034, 1051, 1052, 1106, 1130, 1180, 1220, 1248, 1273, 1305, 1314, 1341, 1342, 1354, 1367, 1369, 1387, 1397, 1405, 1408, 1453, 1454, 1455, 1456, 1472, 1478, 1480, 1482
Survivor . . . . . 565, 618, 656, 1044, 1056
Sustain talk . . . . . 1175
Sympathetic activation . . . . . 1046, 1047, 1061, 1075, 1098, 1103
Systematic desensitization . . . . . 606, 612, 623, 673, 681, 698, 1433
Systematic review . . . . . -12, -9, 124, 128, 167, 227, 233, 340, 364, 407, 410, 431, 437, 455, 566, 568, 590, 596, 652, 665, 747, 1087, 1096, 1105, 1130, 1133, 1150, 1331, 1366, 1431, 1436, 1437, 1438, 1439, 1440, 1441, 1442, 1443, 1444, 1445

## T

Teacher consultation . . . . . 1220, 1399
Technical eclecticism . . . . . 84, 96, 166, 1273, 1279
Telehealth and privacy . . . . . 
Teletherapy . . . . . 189, 190, 1326, 1327, 1328, 1330, 1331, 1352, 1381
Temperament . . . . . 379, 561, 821, 829, 1447
Terminal illness . . . . . 338, 341
Termination . . . . . -13, 207, 212, 335, 344, 945, 951, 979, 981, 1123, 1128, 1221, 1312, 1313, 1314, 1316, 1318
Termination session . . . . . 546, 594, 1315
Theoretical integration . . . . . 84, 166, 1273, 1431

Theory-driven group work . . . . . 116, 189, 364, 1145, 1386, 1393
Therapeutic alliance . . . . . 100, 166, 180, 181, 182, 183, 193, 195, 208, 216, 260, 306, 560, 688, 976, 1250
Therapist competence and fidelity . . . . . 218
Therapist effects . . . . . 1274
Thought record . . 94, 160, 169, 277, 279, 290, 447, 450, 453, 456, 457, 458, 461, 470, 471, 472, 473, 474, 479, 480, 481, 482, 484, 486, 521, 608
Token economy . . . . 163, 259, 614, 626, 705, 709, 714, 715, 716, 721, 730, 763, 765, 766, 767, 769, 771, 774, 775, 779, 782, 783
Transactional . . . . . 284
Transactional analysis . . . . . 400, 401, 402, 403, 404, 406, 407, 409, 410
Transference . . . . . 184, 447, 1146, 1216, 1221, 1223
Trauma
Trauma phases . . . . . 543, 1044, 1048, 1061, 1064, 1095, 1096, 1100, 1101, 1102, 1110, 1434
Trauma-informed care . . . . . -13, 99, 103, 146, 160, 163, 171, 362, 364, 371, 378, 385, 387, 393, 584, 586, 592, 596, 610, 656, 1030, 1044, 1045, 1046, 1051, 1054, 1055, 1056, 1057, 1165, 1223, 1275, 1339, 1352, 1354, 1394
Treatment fidelity
Treatment outcome . . . -3, 91, 96, 206, 231, 243, 322, 407, 516, 523, 822, 835, 842, 891, 997, 1001, 1007, 1125, 1193, 1277, 1432
Treatment outcome measure . . . . . 191, 205, 210, 214, 215, 218, 227, 232, 238, 241, 364, 386, 407, 477, 653, 686, 747, 801, 808, 835, 842, 1001, 1055, 1074, 1076, 1326, 1366, 1391
Treatment plan . . . . . -8, 132, 155, 256, 263, 277, 300, 489, 638, 651, 668, 701, 733, 759, 786, 795, 796, 801, 814, 848, 876, 903, 931, 961, 987, 1013, 1040, 1067, 1091, 1116, 1137, 1154, 1169, 1185, 1212, 1226, 1240, 1253, 1267, 1282, 1286, 1292, 1308, 1321, 1334, 1347, 1353, 1360, 1366, 1374, 1391, 1469, 1482
Triangulation . . . . . 165, 189, 449, 463, 475, 820, 824, 827, 828, 830, 832, 833, 834, 836, 841, 845, 858, 862, 1354

## U

Unblending . . . . . 422, 424, 426, 433, 435
Unconditional positive regard . . . . . 116, 163, 185, 259, 309, 311, 312, 317, 318, 319, 320, 499, 520, 524
Unique outcomes . . . . . 991, 993, 995, 996, 998, 999, 1001, 1006, 1010, 1432

## V

Vagal . . . . . 1046, 1047, 1052, 1053, 1061, 1096, 1097, 1098, 1103, 1164
Validity . . . . . 227, 229, 239, 241, 516, 523, 652, 681, 831, 883, 1299, 1479
Values clarification . . . . . 542, 543, 547, 548, 551, 552
Vygotsky . . . . . 279, 294

## W

Window of tolerance . . . . . 168, 371, 393, 744, 1047, 1050, 1061, 1074, 1095, 1109, 1158, 1160

## Y

Yalom . . . . . 331, 332, 334, 335, 336, 337, 339, 341, 343, 346, 348, 1432

## Z

Zone of proximal development . . . . . 212, 215, 279, 294, 337, 472
